HYDATID TUMORS IN THE BRAIN[1]

BY K HARVEY REED, M D,
OF MANSFIELD OHIO

By the term hydatid tumors in the brain, we mean the intra-cranial occurrence of either the echinococcus or the cysticercus cellulosæ in man The former is the embryo of the tænia echinococcus which has never been known to attain maturity except in the dog The latter is the embryo of the tænia solium, which is most frequently found in man, the hog, and the rabbit, but not unfrequently in the dog and the common rat, and has been known to exist in the ape, the bear, and the deer

The history of these strange parasites is only traceable to the oblivion of the unknown, before the time of Aristotle they were known to be associated with hydatid tumors, and were so regarded by Hippocrates, although it was left for Pallas to describe the echinococcus as a separate parasite, in 1766, and for Goze to observe the same of the cysticercus in 1784

The Mosaic law, which denounced as unclean all those animals which split the hoof and did not chew the cud, or those which chew the cud and did not split the hoof, was undoubtedly based on the existence of these parasites, for it is a well known fact that the hog, and a species of hare common in the east, were particularly rife with the disease produced by these parasites Nor were all the animals considered clean by the Mosaic law even free from this loathsome disease, for we find, on referring to the older works on sheep husbandry, the same disease treated of, under the synonyms of "turnstick," "sturdy," and "staggers," and more recently as "hydatid polycephalis cerebrais," which proved to be very fatal in the flocks where it prevailed, and was described as a many-headed hydatid, each of which was mounted with a disk of sharp hooklets The development of these parasites from the tape worm through all their multiple metamorphoses until again a tapeworm, was for a long time enshrouded in mystery, and it was not until comparatively recently that all the links in the chain were finally united

In order that our subject proper may be better understood we will give but a brief outline of the development of these tæniæ, which, during a certain stage of their development, may form cysts in the brain, or its membranes, of man From Kuchenmeister, the eminent German authority, we have crystalized the following

Division A —Tænia echinococcus 1 Is found only in the dog, has but four joints, the last of which contains the genital organs, and also the ripe eggs 2 When these eggs find their way into the stomach of man they migrate, as soon as germination takes place, through the system and there develop the echinococcus which first form the so called mother, or brood cysts 3 These mother or brood cysts may develop as follows (*a*) The scolices or heads, directly from the mother cysts, when they are called echinococcus scoliciparіens, and is frequently known under the name of E veterinorum, owing to its frequent occurrence in the domestic animals, and is distinguished from the fact of its having from 28 to 36 hooklets (*b*) The mother cysts may develop daughter cysts or even granddaughter cysts, and from either of these latter cysts may develop the scolices, in which case they are called the E altricipariens, and from their frequent occurrence in man they are also known as the E hominis, and can be distinguished by the fact of their having from 46 to 52 hooklets (*c*) The mother cysts may develop scolices externally, as is generally the case in animals, and from this fact they have received the name of exogens (*d*) Or the mother cysts may develop scolices internally as is most frequently the case in man, when they are termed endogens (*e*) Lastly, the mother cysts may not develop scolices at all, when they are known as acephalocysts

When these cysts or their scolices find their way into the stomach of the dog they develop into the tænia echinococcus, but should they find their way into the stomach of any other animal they will not reach maturity, although the embryo in the form of hydatid cysts will develop in man, as well as others of the animal kingdom, and will live in this embryonic state for years, or until it destroys the life of its host, yet it has only been known to reach maturity when eaten by the dog

Division B —Tænia solium 1 It is found in man and the hog, and when matured gives off proglottides or the so called joints, which, like the last segment of the tape-worm of the dog, contains the genital organs and the matured eggs 2 These entire segments, or only a part of the eggs, may find their way into the stomach from which, in an embryonic state, they migrate into the system, and there develop into the cysticercus cellulosæ, which passes through a series of metamorphoses similar to that of the echinococcus

---

[1] Read in the Section of Practical Medicine Materia Medica and Physiology at the Thirty Sixth Annual Meeting of the American Medical Association

The so-called "measly" pork owes its peculiarities to the presence of these cysticerci, which, when eaten by man or other animals, will develop into a tænia solium, or tape-worm Although we have two distinct species of tænia which give rise to hydatid tumors, and furnish a wide field for study, yet we do not think a special study of either, except so far as they interest us clinically, is within the province of this paper, and would respectfully refer those who care to look up the subject in detail, to Kuchenmeister or Leuckart From a clinical standpoint it matters but little which species is producing the intrusion on the economy, the results to the patients are the same

It is true, as a rule, that the cysts or hydated tumors produced by the echinococcus are larger than those produced by the cysticerci, yet the latter make up for the deficiency in size by multiplicity in numbers When hydatid tumors are opened and their contents examined with the microscope they may be found to contain complete scolices or just the scattered hooklets of broken and incomplete heads When scolices cannot be found free in the liquid of the cyst, they may be found by examining the brood capsule, or lining membrane of the same, except in the case of acephalocysts when no scolices or isolated hooklets can be found These hydatid tumors contain a pale straw-colored fluid which usually contains no albumen, is freely charged with chloride of sodium, and contains a liberal quantity of succinic acid, which is not unfrequently found combined with lime or soda, also, traces of grape sugar, together with other chemicals, are generally found present

Hydated cysts of one or the other of these tænia have been found in almost all parts of the human economy, but especially in the liver, the cellular tissue, the brain, the spinal cord, the eye, the spleen, the lungs, kidney, supra-renal capsules, heart, and even in the osseous system

Kuchenmeister, who collected 88 cases of cysticercus of the brain, found the cysts 49 times in the membranes, six of which were on the dura mater, 11 on the arachnoid, 23 on the pia mater, and 9 on the choroid plexus Fifty-nine on the surface of the cerebrum, 41 in the cortical substance, 19 in the white substance, 18 in the ventricles and aqueduct, 17 in the corpora striata and anterior commissure, 15 in the optic thalami and gray commissure, 4 in the corpora quadrigemina and the pineal gland, twice each in the trigona olfactoria, corpus callosum and medulla oblongata once in the olivary body, and 18 times in the cerebellum In the above, 18 per cent were without any symptoms, in 6 they were only trifling, in 5 epilepsy alone was present, in 4 epilepsy with mental debility, in 15 epilepsy with paralytic symptoms, in 24 insanity without epilepsy, of which 7 were without motor or sensory disturbances, 17 had lameness, cramps, hemiplegia, paralysis and muscular twitchings, while out of all only 24 had epilepsy

The size and growth of these hydatid tumors varies according to the space afforded them for development It seems that their size depends more on the pliability of the tissues, rather than the quantity and quality of the nourishment furnished The danger attending the presence of these hydatid tumors depends very much on their location and size When they occur in the subcutaneous cellular tissue it is not attended with any great danger I know of a young man who is under the care of my friend Dr J W Craig, in whom they can be counted by the hundreds, notwithstanding the doctor has cut out several scores already, and yet the young man is apparently in good health When they occur in the muscular tissue they become more and more injurious in proportion to their depth and the importance of the structures involved Their occurrence in the anterior chamber of the eye may not occasion any grave symptoms, but when they occur in the posterior chamber, the vitreous, the retina, or under the retina, as observed by Sommering, Schott, von Graefe, Mackenzie, Baum, Esthlin Sickel, and others, they produce the most serious trouble When they locate themselves in the brain or its membranes, they occasion a multitude of symptoms, which are modified by their location, as will be best observed in the cases I am about to report in this paper, and which, it will be readily observed, renders the diagnosis exceedingly difficult and obscure

Case I —Dr B , æt 46, a large, strong hearty man, who was engaged as a traveling doctor, was taken ill in the summer of 1880, at first was easily fatigued, mentally and physically, but able to be up and around and practice his profession, which was soon *followed with general malaise, which gradually grew* worse until he had lost all inclination for business, this was followed by gradually increasing vertigo, could not sit upright long at a time, which became so bad as to almost disable him from walking across the room, or sitting up at all when he attempted to walk would pitch forward on the face As the disease grew worse he was taken with vomiting, with or without food, which assumed a reflex character From the first there was a constant tendency for the head to drop forwards, and toward the last, when not lying down, would sit with the head dropped forward, which tendency manifested itself even when lying down He was extremely nervous, and toward the last his appetite, which had gradually failed him from the first, failed entirely, except that he had an incessant desire to drink milk, which was immediately vomited after entering the stomach The bowels were regular and urine normal There was a gradually increasing stupor, with some mental aberration toward the last, which continued, together with an increase of all the other symptoms, until the patient died from collapse March 3d, 1881 The post mortem revealed sclerosis of the gray portion of the brain, with softening in the right cerebellum and in both ventricles In the right lateral ventricle was found a hydatid tumor the size of the first joint of a man's thumb, which was surrounded with some pus and considerable effusion

Case II —J W K , æt 28, a strong, hearty laborer, was taken sick in spring of 1879 with pain in the left side No difficulty with the hearing, complained of trouble from coughing with pain in the chest , partial paralysis of right arm In February, 1881 had a similar attack , also one in 1882, which was followed with another in December, 1883, when he commenced to have an offensive discharge from the left nostril In May (23d), 1884, he was taken with a chill, followed with pain in the left side of the head Had a troublesome cough of a nervous character , appetite good, which continued to the l ith no vomiting , bowels regular , no alteration of the ture, but some nervous excitability of the pulse, which rise above or drop below the normal, and in a shc to the normal again Would often complain of the top or left side of his head Was troubled diplopia, and flashes of light in l h eyes Had do manual labor, however, between each of the other attacks, and even up to the commencement of this last attack, at which time he had an exaggeration of all the former symptoms excepting the paralysis but more especially the pulmonary symptoms, which gave rise to coughing and dyspnœa These symptoms increased until he died from general exhaustion June 1st, 1884 Assisted by Dr J Harvey Craig I made a post mortem five hours after death, and found a large hydatid tumor located in the left lateral ventricle, nearly as large as a hulled white walnut There was considerable effusion, with softening and destruction of the brain substance on the left side, and thickening of the membranes of the cerebellum and spinal cord, with here and there spots entirely destroyed by softening An examination of the rest of the body revealed nothing of an abnormal character

CASE III —O H B , æt 52, a strong, robust man, was accustomed to doing considerable mental and physical labor Commenced complaining in the spring of 1882, with general debility accompanied with some dyspnœa and difficulty in deglutition, but had no trouble digesting his food after getting it swallowed , bowels were normal, and urine natural at first, but contained some albumen toward the last Was advised to take a trip for his health, but returned feeling worse , both the asthmatic symptoms and the difficulty in swallowing were much worse His gait became unsteady and staggering, but no paralysis, and mind clear and no tendency to spasms These symptoms gradually became worse until the patient died of exhaustion December 30, 1883 The post mortem showed evidence of athoromatous degeneration of the cerebral arteries, more especially those in the circle of Willis, but little effusion Two hydatid tumors were found in the right lateral ventricle, and three in the left lateral ventricle, varying in size from a grape down to that of a pea

CASE IV —Mrs McS , æt 57, an ordinarily healthy female, had been married and raised a family, but was now a widow , had "changed life" at the age of 50 Had not been feeling well for some time, but commenced to grow worse in 1877, when she was very much debilitated , some mental aberration, among the first of which was that of imagining she smelt the fumes of a tobacco pipe She next became contrary in almost everything, which was the more noticeable on account of her previously agreeable disposition she imagined every person wanted to poison her Her general lassitude increased, her gait became staggery, and she soon lost all ability to maintain the upright position, and when attempted, had a tendency to pitch forward , complained constantly of a cold spot on the top of her head She had a constantly sick stomach, with vomiting only toward the last , a constant desire to urinate, was very thirsty and drank a great deal , had some fever at times in the latter part of her illness , toward the last the pain in the head subsided , had great difficulty in deglutition, very great dyspnœa, some paralysis on the right side A week before she died became blind and deaf, with complete aphasia, and finally went into a comatose condition and died March 12th, 1884 The post mortem revealed two hydatids in the right and three in the left ventricle, with marked cerebral effusion and general softening of the entire brain substance

For the first, third and fourth cases I am indebted to my personal friend and fellow townsman, Dr J W Craig, although the writer was present at the necropsies of all excepting case No III, but had the pleasure and profit of examining the tumors removed in that case

In our opinion, the first and second cases were produced by the ecchinococcus, while the third and fourth were the result of the cysticercus cellulosa

By permission I quote from a private letter received from Prof Wm Pepper, of the University of Pennsylvania, in which he says "I have met with two cases, but unfortunately, the clinical records are so imperfect that I shall not publish them The autopsies were, however, carefully performed There was one hydatid in the retina in one case, with a cyst in the right anterior lobe of the brain In the other the cysts were found on the left side of the base They were both hospital cases, and no record could be obtained as to their previous history The one is undoubted as to its character, while in the other it is believed that the cysts were hydatid from their general gross appearance "

For a number of the following synopses of interesting cases of hydatids of the brain and spinal cord, I am not only indebted to my personal friend, Dr N Senn, of Milwaukee, for kind assistance in collecting them, but also for their translation, also to Dr Robert Herdegen, of Milwaukee, for his assistance in the same

Dr J Klob reports two cases of cysticercus cellulosæ in the brain, in the *Vienna Weekly*, Nos 8 and 9, 1867 The first case was that of a man aged 54, who two years previously suffered from rheumatic pains in the lower extremities For some time gradual loss of memory Pupils somewhat dilated, speech slow, but plain, difficulty in hearing, movements of the upper extremities slow and with effort, toward the last the patient was troubled with incontinence of urine, lower extremities paralyzed A post-mortem examination showed the dura mater to be tense, brain swollen, left hemisphere of the brain somewhat larger than the right On opening the left lateral ventricle, a large cyst with delicate walls escaped, which contained a clear, watery fluid The cyst was as large as a medium sized apple From the under surface a pedicle of gray color was given off, to which two smaller cysts were attached A peculiar pigment was observed, arranged symmetrically, in the centre of which were found the hooklets of the cysticercus

The second case was a woman 43 years of age, who after intense fright suffered from severe headache and a few days later was seized with convulsions These convulsions appeared at short intervals, and assumed an epileptiform character The convulsive movements affected mostly the left side of the body On the eleventh day of illness she died, death being preceded by collapse and stupor On post mortem examination the dura mater was found tense In the pia mater, over the right cerebrum, were found chalky nodules, which were identified as cysticerci which had undergone calcification On the lateral surface two recent cysticerci were found In the posterior portion of the right side of the brain a closed cavity the size of a walnut was found, which communicated with another cavity the size of a pea by a narrow channel At the point where both of these cavities joined was found a calcified cysticercus

Drs W and G Merkle report a case of cysticercus cellulosa in the cerebellum in the German Archives of Clinical Medicine, vol iii, p 297, in which the patient was a strong boy of 13, who was taken ill with severe pain and stiffness of extensor muscles of the neck, which abated slowly and imperfectly After a few months, severe attacks of headache were complained of, which were accompanied at times by vomiting These severe attacks were succeeded by sleep resembling stupor Death occurred suddenly The post mortem revealed in the left lobe of the cerebellum a tumor the size of a hazel nut, with a resistant yellow nucleus The entire white substance of the cerebellum was softened and gelatinous The they migrate into the system, and there develop into the cysticercus cellulosæ, which passes through a series of metamorphoses similar to that of the echinococcus.

The so-called "measly" pork owes its peculiarities to the presence of these cysticerci, which, when eaten by man or other animals, will develop into a tænia solium, or tape-worm. Although we have two distinct species of tænia which give rise to hydatid tumors, and furnish a wide field for study, yet we do not think a special study of either, except so far as they interest us clinically, is within the province of this paper, and would respectfully refer those who care to look up the subject in detail, to Kuchenmeister or Leuckart. From a clinical standpoint it matters but little which species is producing the intrusion on the economy, the results to the patients are the same.

It is true, as a rule, that the cysts or hydated tumors produced by the echinococcus are larger than those produced by the cysticerci, yet the latter make up for the deficiency in size by multiplicity in numbers. When hydatid tumors are opened and their contents examined with the microscope they may be found to contain complete scolices or just the scattered hooklets of broken and incomplete heads. When scolices cannot be found free in the liquid of the cyst, they may be found by examining the brood capsule, or lining membrane of the same, except in the case of acephalocysts when no scolices or isolated hooklets can be found. These hydatid tumors contain a pale straw colored fluid which usually contains no albumen, is freely charged with chloride of sodium, and contains a liberal quantity of succinic acid, which is not unfrequently found combined with lime or soda, also, traces of grape sugar, together with other chemicals, are generally found present.

Hydated cysts of one or the other of these tænia have been found in almost all parts of the human economy, but especially in the liver, the cellular tissue, the brain, the spinal cord, the eye, the spleen, the lungs, kidney, supra-renal capsules, heart, and even in the osseous system.

Kuchenmeister, who collected 88 cases of cysticercus of the brain, found the cysts 49 times in the membranes, six of which were on the dura mater, 11 on the arachnoid, 23 on the pia mater, and 9 on the choroid plexus. Fifty nine on the surface of the cerebrum, 41 in the cortical substance, 19 in the white substance, 18 in the ventricles and aqueduct, 17 in the corpora striata and anterior commissure, 15 in the optic thalami and gray commissure, 4 in the corpora quadrigemina and the pineal gland, twice each in the trigona olfactoria, corpus callosum and medulla oblongata, once in the olivary body, and 18 times in the cerebellum. In the above, 18 per cent were without any symptoms, in 6 they were only trifling, in 5 epilepsy alone was present, in 4 epilepsy with mental debility, in 15 epilepsy with paralytic symptoms, in 24 insanity without epilepsy, of which 7 were without motor or sensory disturbances, 17 had lameness, cramps, hemiplegia, paralysis and muscular twitchings, while out of all only 24 had epilepsy.

The size and growth of these hydatid tumors varies according to the space afforded them for development. It seems that their size depends more on the pliability of the tissues, rather than the quantity and quality of the nourishment furnished. The danger attending the presence of these hydatid tumors depends very much on their location and size. When they occur in the subcutaneous cellular tissue it is not attended with any great danger. I know of a young man who is under the care of my friend Dr. J. W. Craig, in whom they can be counted by the hundreds, notwithstanding the doctor has cut out several scores already, and yet the young man is apparently in good health. When they occur in the muscular tissue they become more and more injurious in proportion to their depth and the importance of the structures involved. Their occurrence in the anterior chamber of the eye may not occasion any grave symptoms, but when they occur in the posterior chamber, the vitreous, the retina, or under the retina, as observed by Sommering, Schott, von Graefe, Mackenzie, Baum, Esthlin Sickel, and others, they produce the most serious trouble. When they locate themselves in the brain or its membranes, they occasion a multitude of symptoms, which are modified by their location, as will be best observed in the cases I am about to report in this paper, and which, it will be readily observed, renders the diagnosis exceedingly difficult and obscure.

CASE I.—Dr. B., æt. 46, a large, strong hearty man, who was engaged as a traveling doctor, was taken ill in the summer of 1880, at first was easily fatigued, mentally and physically, but able to be up and around and practice his profession, which was soon followed with general malaise, which gradually grew worse until he had lost all inclination for business, this was followed by gradually increasing vertigo, could not sit upright long at a time, which became so bad as to almost disable him from walking across the room, or sitting up at all when he attempted to walk would pitch forward on the face. As the disease grew worse he was taken with vomiting, with or without food, which assumed a reflex character. From the first there was a constant tendency for the head to drop forwards, and toward the last, when not lying down, would sit with the head dropped forward, which tendency manifested itself even when lying down. He was extremely nervous, and toward the last his appetite, which had gradually failed him from the first, failed entirely, except that he had an incessant desire to drink milk, which was immediately vomited after entering the stomach. The bowels were regular and urine normal. There was a gradually increasing stupor, with some mental aberration toward the last, which continued, together with an increase of all the other symptoms, until the patient died from collapse March 3d, 1881. The post mortem revealed sclerosis of the gray portion of the brain, with softening in the right cerebellum and in both ventricles. In the right lateral ventricle was found a hydatid tumor the size of the first joint of a man's thumb, which was surrounded with some pus and considerable effusion.

CASE II.—J. W. K., æt. 28, a strong, hearty laborer, was taken sick in spring of 1879 with pain in the left side. No difficulty with the hearing, complained of trouble from coughing with pain in the chest, partial paralysis of right arm. In February, 1881 had a similar attack, also one in 1882, which was followed with another in December, 1883, when he commenced to have an offensive discharge from the left nostril. In May (23d), 1884, he was taken with a chill, followed with pain in the left side of the head. Had a troublesome cough of a nervous character, appetite good, which continued to the last, with no vomiting, bowels regular, no alteration of the temperature, but some nervous excitability of the pulse, which would often rise above or drop below the normal, and in a short time return to the normal again. Would often complain of a cold spot on the top or left side of his head. Was troubled at times with diplopia, and flashes of light in both eyes. Had been able to do manual labor, however, between each of the other attacks, and even up to the commencement of this last attack, at which time he had an exaggeration of all the former symptoms excepting the paralysis, but more especially the pulmonary symptoms, which gave rise to coughing and dyspnœa These symptoms increased until he died from general exhaustion June 1st, 1884 Assisted by Dr J Harvey Craig I made a post mortem five hours after death, and found a large hydatid tumor located in the left lateral ventricle, nearly as large as a hulled white walnut There was considerable effusion, with softening and destruction of the brain substance on the left side, and thickening of the membranes of the cerebellum and spinal cord, with here and there spots entirely destroyed by softening An examination of the rest of the body revealed nothing of an abnormal character

CASE III —O H B, æt 52, a strong, robust man, was accustomed to doing considerable mental and physical labor Commenced complaining in the spring of 1882, with general debility accompanied with some dyspnœa and difficulty in deglutition, but had no trouble digesting his food after getting it swallowed, bowels were normal, and urine natural at first, but contained some albumen toward the last Was advised to take a trip for his health, but returned feeling worse, both the asthmatic symptoms and the difficulty in swallowing were much worse His gait became unsteady and staggering, but no paralysis, and mind clear and no tendency to spasms These symptoms gradually became worse until the patient died of exhaustion December 30, 1883 The post mortem showed evidence of athoromatous degeneration of the cerebral arteries, more especially those in the circle of Willis, but little effusion Two hydatid tumors were found in the right lateral ventricle, and three in the left lateral ventricle, varying in size from a grape down to that of a pea

CASE IV —Mrs McS, æt 57, an ordinarily healthy female, had been married and raised a family, but was now a widow, had "changed life" at the age of 50 Had not been feeling well for some time, but commenced to grow worse in 1877, when she was very much debilitated, some mental aberration, among the first of which was that of imagining she smelt the fumes of a tobacco pipe She next became contrary in almost everything, which was the more noticeable on account of her previously agreeable disposition she imagined every person wanted to poison her Her general lassitude increased, her gait became staggery, and she soon lost all ability to maintain the upright position, and when attempted, had a tendency to pitch forward, complained constantly of a cold spot on the top of her head She had a constantly sick stomach, with vomiting only toward the last, a constant desire to urinate, was very thirsty and drank a great deal, had some fever at times in the latter part of her illness, toward the last the pain in the head subsided, had great difficulty in deglutition, very great dyspnœa, some paralysis on the right side A week before she died became blind and deaf, with complete aphasia, and finally went into a comatose condition and died March 12th, 1884 The post-mortem revealed two hydatids in the right and three in the left ventricle, with marked cerebral effusion and general softening of the entire brain substance

For the first, third and fourth cases I am indebted to my personal friend and fellow townsman, Dr J W Craig, although the writer was present at the necropsies of all excepting case No III, but had the pleasure and profit of examining the tumors removed in that case

In our opinion, the first and second cases were produced by the ecchinococcus, while the third and fourth were the result of the cysticercus cellulosa

By permission I quote from a private letter received from Prof Wm Pepper, of the University of Pennsylvania, in which he says "I have met with two cases, but unfortunately, the clinical records are so imperfect that I shall not publish them The autopsies were, however, carefully performed There was one hydatid in the retina in one case, with a cyst in the right anterior lobe of the brain In the other the cysts were found on the left side of the base They were both hospital cases, and no record could be obtained as to their previous history The one is undoubted as to its character, while in the other it is believed that the cysts were hydatid from their general gross appearance "

For a number of the following synopses of interesting cases of hydatids of the brain and spinal cord, I am not only indebted to my personal friend, Dr N Senn, of Milwaukee, for kind assistance in collecting them, but also for their translation, also to Dr Robert Herdegen, of Milwaukee, for his assistance in the same

Dr J Klob reports two cases of cysticercus cellulosa in the brain, in the *Vienna Weekly*, Nos 8 and 9, 1867 The first case was that of a man aged 54, who two years previously suffered from rheumatic pains in the lower extremities For some time gradual loss of memory Pupils somewhat dilated, speech slow, but plain, difficulty in hearing, movements of the upper extremities slow and with effort, toward the last the patient was troubled with incontinence of urine, lower extremities paralyzed A post-mortem examination showed the dura mater to be tense, brain swollen, left hemisphere of the brain somewhat larger than the right On opening the left lateral ventricle, a large cyst with delicate walls escaped, which contained a clear, watery fluid The cyst was as large as a medium sized apple From the under surface a pedicle of gray color was given off, to which two smaller cysts were attached A peculiar pigment was observed, arranged symmetrically, in the centre of which were found the hooklets of the cysticercus

The second case was a woman 43 years of age, who after intense fright suffered from severe headache, and a few days later was seized with convulsions These convulsions appeared at short intervals, and assumed an epileptiform character The convulsive movements affected mostly the left side of the body On the eleventh day of illness she died, death being preceded by collapse and stupor On post-mortem examination the dura mater was found tense In the pia mater, over the right cerebrum, were found chalky nodules, which were identified as cysticerci which had undergone calcification On the lateral surface two recent cysticerci were found In the posterior portion of the right side of the brain a closed cavity the size of a walnut was found, which communicated with another cavity the size of a pea by a narrow channel At the point where both of these cavities joined was found a calcified cysticercus

Drs W and G Morkle report a case of cysticercus cellulosa in the cerebellum in the German Archives of Clinical Medicine, vol iii, p 297, in which the patient was a strong boy of 13, who was taken ill with severe pain and stiffness of extensor muscles of the neck, which abated slowly and imperfectly After a few months, severe attacks of headache were complained of, which were accompanied at times by vomiting These severe attacks were succeeded by sleep resembling stupor Death occurred suddenly The post-mortem revealed in the left lobe of the cerebellum a tumor the size of a hazel-nut, with a resistant yellow nucleus The entire white substance of the cerebellum was softened and gelatinous The swelling was surrounded by a layer of pus 1 mm in thickness The tumor consisted of a cyst, which contained detritus, in the centre of which a well preserved cysticercus was found

A similar case is reported by G Markle, in the person of a boy 10½ years old, previously in robust health, who was taken ill with headache and vomiting In one of these attacks of headache he became restless and delirious, which was followed by unconsciousness, stupor and death At the necropsy, a cyst the size of a cherry was found in the infundibulum, which proved to be a cysticercus cellulosa The gyri of the brain were flattened, the consistency of the white substance was firm

Dr Marks, in writing of the echinococcus in the brain (Virchow in Hirsch's yearly report, 1873, vol I, p 640) reports a case of echinococcus in the brain which is of interest on account of its location in the left temporal lobe of the brain The patient, who was 40 years of age, had had an attack of dizziness during the month of December, 1871 In July, 1873, he was seized with another attack, which was followed with facial paralysis of the right side, complete paralysis of the left upper extremity, partial paralysis of the left lower extremity Sensation in both right arm and leg diminished His condition both mentally and physically gradually became worse, especially the aphasia He at last passed into a stupor, had incontinence of urine, followed by death The autopsy showed great tensity of the dura mater, the convolutions of the cerebrum were flattened, but more on the left than on the right side On the outer side of the left temporal lobe a green discolored spot the size of a dollar was found, below which, at the depth of 2 mm, an echinococcus cyst the size of a fist was found, which contained a clear fluid The cyst could be removed with ease from the substance of the brain The right half of the pons was flattened, while the remaining portions of the brain were not materially changed

Griesinger, who has collected over 70 cases of these parasitic affections of the brain, 54 of which he describes minutely, 21 of which were his own cases, found their occurrence in the spine very rare, of which Dr Otto Hebald reports two very interesting cases, which are recorded in vol XV, No 3, p 812, of the *Archiv fur Psychiatrie*, Berlin, 1884, for the translation of this, from which I only give a synopsis, I am indebted to Dr Henry Ruess, of Mansfield, Ohio

The first patient was an idiotic female, aged 63, of healthy parentage, but who had an idiotic half-sister Early in life she became hysterical Seven years ago was troubled with hallucinations, a year later was taken with epileptic convulsions, which occurred frequently, together with vomiting, two years later became blind, with partial paralysis, and perverted sensibility, difficult articulation, general depression, followed by death The autopsy revealed cysticerci under the pia mater of the spine and brain, also in the cortex of the latter One was found free in the lateral ventricle, also one in the muscle of the heart and under the pleura costalis

In the same article he reports another case which occurred in a female aged 65, who was of an irritable disposition, especially during the menstrual period, who was taken ill in 1876, showing signs of brain irritation, with hallucinations in hearing At times had attacks of religious exaltations, at others tore her hair, and at times was very destructive After being removed into the asylum her symptoms grew worse would inflict injuries upon herself and others, she was exceedingly filthy, would eat her own and others' fæces In 1877, symptoms of pressure on the brain with epileptic attacks, with unconsciousness, had vomiting of green matter, slight paralytic symptoms in the right upper extremity Her condition, with occasional short improvements, gradually grew worse which was attended with difficult articulation In 1879 partial and total blindness set in, from that time to 1881 and 1882 paralysis of lower extremities, toward the last, in 1883, had to be carried around Epileptic attacks preceded her death, which occurred in the summer of 1883 The autopsy revealed cysticercus the whole extent of the dura spinalis as high as the first dorsal vertebra, also over the right anterior and lateral division of the medulla Marked adhesions of the dura to the cranium Scattered under the membranes and over the brain in both lateral ventricles were cysts of the cysticerci from the size of a pea to that of a bean, which were filled with a clear yellowish liquid Also in the right posterior wall of the chest, under the pleura, were found four cysts about the size of a bean, also one under the left pleura costalis The writer observed that only those in the ventricles were well developed, the rest were imperfectly developed, and that those in the substance of the brain were smaller, and had a tougher capsule A few reached into the white substance of the brain, but not a single one was found there alone, the majority being in the cortical substance of the brain, in different parts of it After making a careful analysis, the author arrives at the conclusion that the case was primarily one of insanity, which led to the eating of fæces, by which she became infected with the cysticerci, which developed a new train of symptoms still later, which subsequently produced death

Ulrich, in abstract in Virchow, 1872, No 2, p 16, reports a case of cysticercus in the brain and spine both, in an insane person Regarding this case, he says the insanity was not caused by the cysticercus, but the cysticercus was the result of the extremely filthy habits of the person

Yates—abstract in Virchow, 1870, No 2, p 60, reports a case of a young man who died at the age of 21, who was under his care for two years previous to his death, and complained of headache, weakness of legs, hemiplegia, light delirium and stupor, followed by death Autopsy revealed a hydatid tumor the size of an ostrich egg in the left hemisphere of the cerebrum The patient died suddenly, but notwithstanding his stupidity, he was able to answer questions intelligently up to the time of his death

Sutherland—in Virchow, 1873, No 2, p 67, reports the occurrence of an echinococcus between the chiasm and pons, with compression of the two oculo motors, and destruction of the ventricles His symp toms were intense headache, frequent vomiting, tinnitus aurium, deafness, and impaired vision

Schlott—in Virchow, 1873, No 2, p 68, reports a case occurring in a former soldier, who took sick with frequent fits of giddiness, headache, nausea, and heaviness of his limbs tongue blue and swollen, oscillations before the eyes, diplopia, staggering gait His bodily and mental capabilities grew weaker first vomiting and regurgitation afterward would swallow with great avidity Spontaneous discharge of fæces and urine, his language became stammering, choreic movements, subsultus tendinum, and finally died with pulmonary œdema The autopsy revealed numberless cysticerci, from the size of a pin head to that of a pea, in the dura over the base of the brain, as well as in the dura of the cerebrum, in the substance of the cerebrum and cerebellum, and also on the surface of the same, and in the ventricles and in the great ganglions, besides, they were even found in the muscles throughout the body

Westphal—in Virchow, 1873, vol 2, p 68, reports an interesting case, with recovery, of echinococcus observed in the Charité, in Berlin, in a young man aged 17 The symptoms were headache, nausea, right exophthalmus, and protrusion of the right temporal bone, hemiplegia on the left side These symptoms came on step by step, with exacerbations and remissions The protrusion of the right parietal region became large, extending to the vertex In four weeks after he entered the hospital, by the finger one could feel a perforation of the bone about an inch above the outer angle of the right eye, four days later there was another perforation near the first one By and by, from these openings a fluctuating tumor appeared under the skin, and the tumor was diagnosticated echinococcus An exploratory puncture failed, and an incision was made, which soon discharged about ninety cysts Ten days later, by blowing his nose there came out of the left nostril a large and two smaller cysts When the patient left the hospital a few weeks later, he was free from headache and hemiplegia, but the circumference of the right side was three inches larger than the left, and the exophthalmus still continued, with blindness The openings in the bones still existed, the pulse varied from 90 to 150, with a normal temperature

Eichorst, vol II, page 708, says the echinococcus usually consists of but one cyst, seldom multiple, but in the case of Espinosa there were 52 cysts under the arachnoid membrane

The frequency of this disease depends on at least three factors 1, The prevalence of making dogs household pets, as in Iceland, where it is estimated by some writers that at least one-tenth of the population suffer from echinococci, which is undoubtedly due to this cause 2, The eating of half cooked "measly pork," which gives rise to numerous tapeworms, and they in turn to the cysticerci 3, The filthy habits of many, together with the increase of population, which necessitates the close commingling of all classes

Hydatid tumors are found to be more frequent in old persons than in young persons, although they may occur at any age, and are more apt to be found among the poorer members of the population than among those in affluent circumstances, but sex does not appear to make any difference as to their frequency The tape-worm and its embryo may exist in the same person at the same time, or a tape-worm and the echinococcus may exist in the same subject at the same time, but a tænia echinococcus and its embryo never has been known to exist in man at the same time The prognosis in this disease as a rule is unfavorable when it is intra cranial, only a few such cases of recovery are on record

The treatment of these cases is also very unsatisfactory so far as therapeutic remedies are concerned The salts of mercury and iodide of potassium have been, however, liberally used, with a view of destroying them by their antiparasitic effects, as well as for their alterative virtues Tr of kamala, in doses of from 30 to 40 drops three times a day, has been used freely with some reputation for good Electricity has filled its place in the catalogue of remedies used in this malady with a questionable reputation

When accessible the most positive benefits are derived from surgical interference, by which the cysts are emptied, by laying them open with the bistoury, and now that surgeons are beginning to deal with the brain as with other parts of the human economy, and more and more liberties are taken with it annually it is hoped that sufferers from this dreadful disease may find a source of relief ere long at the hands of the skillful surgeon

Although this disease, except in Iceland, is comparatively rare, and perhaps more so in America than in continental Europe, yet Dr Osler states, in regard to the echinococcus disease in America, that he has collected from various sources 61 cases (See transactions of Canada Med Association, 1882, p 354)

With the steady increase of our population, unless active preventive measures are inaugurated we must expect a corresponding increase in this disease, which will steal in on us as a thief in the night, and cause many a premature death, unless we remove the causes which favor its production and development, viz Dogs as household pets, the use of half-cooked unhealthy pork, together with all general unsanitary surroundings

April 20th, 1885

HOW SOON AFTER EXPOSURE TO SEPSIS MAY THE ACCOUCHEUR RESUME PRACTICE?[1]

BY GEO F FRENCH, A M , M D ,

OF MINNEAPOLIS MINN

The term puerperal fever embraces a group of essentially diverse affections, some of which are, unquestionably, non-contagious, the septicæmic variety of the disease is that which alone engages us in this discussion An estimate of its gravity may be deduced from the statement of Barker that since 1740 there have been more than two hundred epidemics of this disease This fact sufficiently emphasizes its prevalence, and the mortality attending many of these epidemics stamps the disease as a scourge scarcely less terrible than cholera or smallpox It is most humiliating, in view of the fact that puerperal fever is largely a preventable disease, caused too often by criminal negligence on the part of physician or nurse

---

[1] Read in the Section on Obstetrics and Gynecology at the thirty-sixth Annual Meeting of the American Medical Association

It is frequently urged that our science is not an exact one, but it seems to me the evidence that this fever may be caused by the contagia of erysipelas, scarlet fever and septic dirt, is as demonstrable as any proposition of Euclid It is now more than thirty years since Semmelweiss proclaimed to the profession that "one source of puerperal fever is decomposing organic matter" There is scarcely a hamlet in the land where instances of fatal puerperal infection have not been known, by the profession, to be traceable to avoidable sources, and there are few of us who have done service for a score of years, who have not been cognizant of such cases, which intelligent and conscientious vigilance might have prevented And yet I have heard of no one imitating the example of the conscientious Michalis, who expiated his offence with his life If death be the penalty of homicidal ignorance, what shall it be for criminal carelessness? In the whirl of crowded professional work, some plead lack of opportunity to carry out the tedious and painstaking details of the disinfecting process, but how valid would such excuse appear in the case of wife or sister, or in the eye of the law? The great Simon sententiously remarks "Contagia are perhaps the most important of all the incidental physical influences which concern mankind," and Hebra says the discovery of Semmelweiss as to the chief source of puerperal fever, ranks in importance with that of Jenner

In order to obtain all possible light on the duty of the practitioner to the obstetric patient, I addressed in October last letters of inquiry to some of the most distinguished medical men in this country and in Europe, of which the following is the substance "How soon after exposure to sepsis may the accoucheur resume practice? My purpose is to controvert the opinion which obtains in the profession, that *time* is an essential element in the cleansing process I have had an experience which emboldens me to make abdominal section on the day following exposure I greatly desire to know whether your experience warrants me in pursuing and advocating such a course"

In reply the following communications were received I omit all portions purely personal

In my opinion, the element of time *is* essential

HENRY SAVAGE

Samaritan Free Hospital for Women and Children, London, November 3 1884

In reply to yours of October 16, I beg to inform you that I consider time an all essential element in the cleansing process

The fixing of any definite limit is a difficult one, both for abdominal surgery and midwifery Our Samaritan Hospital rule is a week, and certainly I think that this is short enough "An experience" is of course valueless The general experience is the only guide I do not think the profession generally sufficiently careful on this point, or sufficiently alive to the extreme danger of neglect J KNOWSLEY THORNTON

London November 28, 1884

From Freiberg, November 6, 1884, HEGAR writes

The question laid before me is difficult to answer Proof is not exact as to how the septic germ behaves with reference to heat, light and disinfection From a purely theoretical standpoint, the question cannot be answered so far as concerns experience, opinions differ The one observes we should avoid for some time operations where infection is easily communicated, the other thinks we can perfectly cleanse ourselves Moreover, the last give tedious directions as to the disinfecting

I dare not decide between them, whether a perfect cleansing is possible or not In my experience, it is difficult, one must be extremely careful I think that in general we shall do well to avoid for two or three days operations in which the danger of infection is very great, as in laparotomies That with the avoidance careful cleansing is not unnecessary, is understood Were I or a relative to undergo an operation, I should, *ceteris paribus*, choose the surgeon who, for several days, had had nothing to do with septic material

The foregoing opinions, differing widely from my own, certainly carry with them the weight of high authority

Let us consider some of the notions regarding contagion which once prevailed, and compare them with opinions now held A century ago, a belief obtained even among the *savants* of the profession, in what was called a lousy distemper, supposed to be spontaneously generated in the body by cachexia or bad humors (Fuchs) Devergie held that innutrition led to the development of lice According to Husemann, the emperor Arnulf's death, and that of one of the Danish kings, was ascribed to the lousy distemper Colonies of such vermin, in macroscopic legions, were believed to be entrenched under the skin so that it was impossible to dislodge or exterminate them It was manifestly ineffective to destroy by disinfectants those on the surface, because in a few hours their place was supplied by fresh eruptions from within These ideas have been succeeded in the profession by vague fancies that are the legitimate offspring of these superstitions There is a dread of some supernatural presence, alike invisible and invincible

When for years puerperal fever hovered like a spectre over the practice of Dr Rutter, and neither art could cleanse him nor science explain the nature of his leprous influence, Dr Meigs reverently observed that he was "merely unhappy in meeting with such accidents through God's providence" So long as a disease is controlled by an unknown power, it is formidable, as soon as it is traceable to natural causes, it is shorn of its terrors Dr Rutter, as an object of superstitious fear, was a plague-stricken spot in the profession, but as a simple case of ozœna, he was no longer an object of consternation

The present weight of evidence goes to show that the *materies morbi* of contagion, whether living or dead, is a non gaseous particle, capable of being acted upon and demonstrably susceptible of destruction Its material nature makes it amenable to material and human influences Several kinds of contagia have been isolated, and their property of self multiplication demonstrated It has been exactly determined how such contagia are affected by chemical and various other agents The longevity of the bacillus is not to be determined by the duration of its individual life, but by the fact of its infinite multiplication and the unending existence of the organism through its spores I am told that Pasteur has spores which have been preserved twenty years Clinically this has been too frequently illustrated by repeated outbreaks in non disinfected houses of diseases like diphtheria and scarlet fever, after long intervals Murchison and Richardson report cases where disease had become so fixed in certain houses, that succeeding families and tenants were attacked, though many months intervened between the various occupancies Hildenbrand's coat, according to Professor Louis Thomas, "retained its contagion for a year and six months" The tenacity of life of certain forms of contagia is expressed and emphasized by the opinions of those who believe that they cannot be immediately destroyed by any known means Experiments by Arloing, Thomas, Koch and Sternberg, show that the resting spores of the bacilli are the most difficult of all forms of life to destroy requiring a solution of corrosive sublimate 1–5000, while ordinary spores are killed by a solution of 1–20000 Steam or boiling water kills all bacteria and spores in ten or fifteen minutes Filth, undergoing putrefactive or fermentative change, is most conducive to the spread of infectious diseases

Particles of contagion most often find lodgement on our hands, and particularly under the finger nails It is always possible after the ordinary use of the nail brush or knife, to remove particles of dirt, in which the microscope reveals living germs of possible infection On this account, I cut the nails short, and swab under them with a blunt instrument covered with cloth, and wet with some disinfecting liquid I formerly used for this purpose, a 5 per cent solution of carbolic acid, but this made the sensitive flesh crack and pull away from the nails, I now use instead, corrosive sublimate solution 1 2000—The 5 per cent solution of carbolic acid, even in washing the hands, causes them to crack and chap so as to be an open source of infection to the operator Before I adopted the swabbing under the nails, I covered the interspace with collodion, the use of which I now reserve for hang-nails, cracks and abrasions All instruments are kept scrupulously clean as well as disinfected, and the nurse is regarded as one of the instruments

Time is essential so far as it is requisite to make the cleansing process thorough and complete, but time alone is important to effect anything To me, the most impressive contribution to the study of this subject, the most practical in method and most telling in results, was a paper in a June, 1880, number of the *Centralblatt für Chirurgie*, by Volkmann — "May a surgeon or obstetrician undertake post mortem examinations?" Beside the usual method of cleansing the hands, he guards against infectious emanations from the clothing, by wearing a fresh linen coat Spectators at laparotomies are furnished with similar coats, and instead of being asked whether they have been attending erysipelas, etc , and thrown on their honor, they are disinfected in an adjoining room, under the supervision of an assistant Cleanliness is a trait of personal character, and it is as impossible for some men to be absolutely clean, as it is for them to be orderly or systematic Such physicians are disqualified for ovariotomy, or even obstetric work

To show my confidence in the possibility of immediate absolute disinfection, I made the following experiments

June 21, 1884, after laying open a dissecting abscess of the thigh in a pyæmic patient, and stripping the limbs with both hands, till they were offensively drenched with pus, I scrupulously disinfected myself, and three hours later, attended Mrs M in confinement

July 22, 1884—In dealing with a case of pyonephrosis, before penetrating the kidney, I came upon a foul perinephritic abscess, passing through this, the kidney was sought, incised, explored and its grumous contents scooped out with the finger The hand was so long engaged in this work, that a more complete purulent saturation could hardly be conceived In the afternoon of the same day I confined the wife of a physician, after stating to him the full extent of my morning exposure In both of these cases, the convalescence was perfectly normal

February 11—I purposely infected my index finger with the ichor of erysipelas, and after a corrosive sublimate wash, inserted it into a fresh wound, from which I had just excised a tumor I might indefinitely multiply instances of this kind But I will present opinions which to my mind are *ex cathedrâ*

> I have done what you have done, without bad consequences, and I fully agree with you in your conclusions
>
> Wm Goodell
>
> Philadelphia, October 25, 1884

> In our pure atmosphere, I have never declined obstetric work on account of septic exposure, and have never had an accident
>
> Robert Battey
>
> Rome Ga , October 3, 1885

> I have done no obstetric practice in twenty years, but judging from a surgical stand point, I would say that the interval might be a short one, after the free use of soap and water, the nail brush and a change of clothing T A Emmet
>
> 89 Madison avenue, New York, February 25, 1885

> I quite agree with your premises Time, is an uncertain, and may be, a dangerous factor to place trust in I do not question the wisdom of general rules of Hospital practice, and until we know something of the real sources of danger, it was wise to make time a consideration I think now our general knowledge of the particular *materies morbi*, quite sufficient to allow the intelligent *believer* to so care for himself, that he may safely be able to operate as you have done I am not aware that I have infected an individual since I made a careful study of the subject
>
> Henry O Marcy
>
> Boston, December 6, 1884

Most of us recall the memorable paper of Prof Thomas, read in December, 1883, before the New York Academy of Medicine, in which he describes his method of disinfecting himself, in the the short interval, between a case of puerperal septicæmia and a Tait's operation Physicians from Main to California were interested in that particular operation Dr Thomas subsequently informed me, that the patient recovered without a bad symptom

The following letter is from Prof Martin, of Berlin, dated December 7, 1884

> According to my experience, we are able to disinfect ourselves sufficiently, so that we can resume practice very soon after an exposure to sepsis The chief question is, What are the best means of disinfection? For the entire body, a lotion of corro

sive sublimate 1–10000, for the hands, 1–1000 This has been my custom when I have been obliged to make an abdominal section the day following exposure to septic infection I believe that a night's rest in bed, is an important adjuvant My friend, Dr Carl Ruge, on two occasions, was summoned from an autopsy to the bedside of a parturiant, and under protest, introduced his hand into the uterus He had cleansed his hands with corrosive sublimate, and no evil results followed The untorn uterus, even when puerperal, is not so susceptible to septic infection as the peritoneum, which should not be touched until there has been a general ablution both with soap and corrosive sublimate The great question is, Who is able to disinfect properly? And the answer to this question is quite an individual matter

Dr Carl Schroder writes, under date of December 4, 1884

In my opinion, withdrawal from practice is not necessary, but can be resumed after a thorough cleansing

Prof Nussbaum writes from Munich, November 8, 1884

I have very often made ovariotomies with the best results, the day after a post mortem, but I have always made a thorough disinfection of my hands, and changed my clothes
GEHEIMRATH VON NUSSBAUM

At the beginning of this paper, I referred to the noteworthy publication of Prof Volkmann in the *Centralblatt fur Chirurgie* of 1880 In his letter to me, dated Halle, December 5, 1884, he says

I hold the same views to day as at that time A surgeon who *disinfects* himself *well*, can immediately after making a post mortem examination, or dressing a septic wound, undertake a laparotomy, do a trepanning, examine a patient with a fresh complicating fever, or dress a penetrating wound of the joint Every morning from six to eight, during the summer, I am obliged to give the students operations on the cadaver, and from ten to three, I am busy in the Hospital operating and dressing wounds, and I have never yet infected a patient In the winter, I have no operations on the cadaver to make Comparing my results in the clinic, I can assure you, that the mortality in summer is not greater than in winter
RICHARD VOLKMANN

In conclusion, I present the following characteristic reply, which epitomizes the subject under discussion

If you have *thoroughly* disinfected yourself, you can immediately enter upon obstetric practice *Time* does not destroy septic dirt
ESMARCH
Kiel, December 5, 1884

GEOGRAPHICAL PATHOLOGY OF CONSUMPTION[1]

BY G W McCASKEY, A M, M D,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST FT WAYNE COLLEGE OF MEDICINE FT WAYNE IND

I

The deaths from consumption in the United States, in the year 1880, numbered 91,551, almost one-eighth the entire mortality from all causes This pregnant fact seems to furnish at once an incentive and excuse for the following endeavor to ascertain what definite relation there is, if any such exists, between this disease and certain climatic conditions in the United States

An obstacle is encountered at the very threshold of the inquiry in our defective system of registration It must be admitted, in the first place, that many cases reported as consumption have no relation to that disease It is also well known that many cases are not reported at all The migratory character of a considerable body of the population—especially its westward flow—is also a disturbing element in a statistical study And, finally, those regions, the climates of which have secured the reputation of being curative of consumption, have their death rate from this disease greatly increased by the immigration of a large number of the rapidly fatal type of cases The last-named source of error can not be removed, as there are no available records of its extent It is only found, however, in a small number of localities, and if it could be entirely removed the only effect, so far as the present study is concerned, would be to increase the force of the conclusions drawn After recognizing its existence, therefore, it may safely be dismissed

So far as the other sources of error are concerned, while their existence is to be deplored, they will not impair deductions made from data which need only be comparatively correct Indeed, for purposes of comparison the absolute death rate is quite unnecessary The death-rates of different localities might just as well be expressed in units, taking as an arbitrary standard either the highest or lowest death-rate found in any given locality, the mean death-rate between these two extremes, or the average of all. There is little doubt that the census report gives data which are at least relatively correct, and which can therefore be relied upon for the purposes of a comparative study The area of the United States is too vast and complicated for detailed analysis within the intended scope of this paper By a general survey, however, certain broad facts may be collated, and certain inferences drawn, which may not be without value

A basis for comparison, at once practical and scientific, is readily formed by placing side by side (1), the mortality from consumption, (2), the mortality from all causes, and (3), the percentage of the former to the latter These data will be ascertained for the United States, for groups of States, for individual States, and, in some instances, for parts of States. Notwithstanding the wide variations found in different parts of these extensive regions, each has its average of annual rain fall, of elevation, of mean annual temperature, and the like, which, taken together, or perhaps singly, are entirely characteristic of itself These distinctions are broad enough to completely overshadow local anomalies, even if these did not, in accordance with a well recognized law, correct one another by mutual antagonisms

With the exception of four states (California, Florida, Louisiana and Pennsylvania) and three territories (Arizona, Nevada and Montana), the death-rate from all causes was larger in 1880 than in 1870 The result of this increase upon the part of the individual states is to raise the death rate of the United States from 13 3 per 1,000 in 1870 to 15 1 in 1880, an increase of 13½ per cent Curiously contrasting with this fact, the death-rate from consumption either shows no change or a slight increase in all except fifteen of the states and territories. The average for the United States, which shows no change whatever, remaining 1.8 per 1,000 for each year, only illustrates and confirms the remark that the local variations neutralize one another, thus making no change in the general result.

---

[1] Read before the Indiana State Medical Association

The following table has been compiled from the census reports for 1870 and 1880.

TABLE I.

Showing death-rate (1) from all causes, (2) from consumption, and (3) percentage of latter to former.

	Deaths per 1000 of Population		Deaths from Consumption per 1000 of Population		Percentage of Deaths from Consumption to all Deaths	
	1870	1880	1870	1880	1870	1880
UNITED STATES	13.3	15.1	1.8	1.8	14.1	12.1

Wyoming	8.1	9.1	.4	.3	5.4	2.6

The well known prevalence of the disease in New England, and its rarity in the south Atlantic and Gulf coast states, becomes at once apparent. It is also observed that, with numerous undulations, it is somewhat evenly distributed over the remaining states east of the 95th meridian. In the vast region west of this meridian, comprising more than one-half the territory of the United States, and about one-fifteenth of its population, it is, with the exception of a portion of California (Texas is included in another division), even less prevalent than in the south Atlantic and Gulf coast states.

The division into groups indicated by the following table is intended to throw together adjacent states which have something in common regarding their consumption death-rate, with the view of studying some of their more important climatic conditions for the purpose above mentioned. The boundary line between these different regions, to be absolutely correct, would often, or perhaps generally, intersect the different border states. The difficulties in the way of securing statistical data for parts of states were so great, however, as to render such a division impracticable. The number of these groups, furthermore, could have been indefinitely increased, often comprising a few counties instead of several states. This could only have led to confusion, and been utterly barren of results.

TABLE II.

Showing death rate (1) from all causes, (2) from consumption, and (3) percentage of latter to former in groups of States.[1]

	Deaths per 1000 of Population from all cause		Deaths per 1000 of Population from Consumption		Percentage of Deaths from Cons'n to Deaths fr. all causes	
	1870	1880	1870	1880	1870	1880
New England States	14.6	16.7	3.0	2.6	20.8	16.1
Middle States	14.9	16.2	2.4	2.2	15.8	13.8
S. Atlantic and Gulf States	12.2	14.6	1.0	1.3	8.1	8.8
Interior and Lake States	11.5	14.6	1.6	1.8	14.2	12.0
States and Territories W. of 95th Meridian except Texas and California	10.8	13.8	0.9	1.0	8.5	7.1
California	16.1	13.4	2.2	2.2	13.8	15.6

Having marked out the different regions for individual study and noted the high mortality from consumption in the New England and Middle states, and the low mortality in the south Atlantic and Gulf states, and the western half of the continent, it now remains to study the climatic conditions of each group in their bearings upon this disease.

Temperature.—Temperature may first be considered, as one of the most prominent factors in that combination of conditions called "climate." The mean annual temperature will be taken as the standard of comparison. In making estimates of the mean annual temperature of a group of states, it should be constantly born in mind, that they are only the averages of more or less widely diverging extremes. The same caution is necessary in considering the like estimates of annual rain-fall, and altitude which are to follow. As absolute measurements, they are not reliable; as comparative statements—and it is for purposes of comparison only that they are introduced—they are believed to be approximately correct. A glance at the isothermal, isohyetal, and hypsometric charts, especially the first two, will illustrate in a very forcible manner, the difficulties encountered. Taking the entire Atlantic and Gulf Coast line, we find a very marked decrease in its consumption death rate as the mean annual temper-sive sublimate 1–10000, for the hands, 1–1000 This has been my custom when I have been obliged to make an abdominal section the day following exposure to septic infection I believe that a night's rest in bed, is an important adjuvant My friend, Dr Carl Ruge, on two occasions, was summoned from an autopsy to the bedside of a parturiant, and under protest, introduced his hand into the uterus He had cleansed his hands with corrosive sublimate, and no evil results followed The untorn uterus, even when puerperal, is not so susceptible to septic infection as the peritoneum, which should not be touched until there has been a general ablution both with soap and corrosive sublimate The great question is, Who is able to disinfect properly? And the answer to this question is quite an individual matter

---

[1] The New England and Middle states were assigned positions as separate groups, partly because of their long recognized geographical unity, and partly because there were no apparent reasons for uniting the two groups or subdividing either. The third group includes the remaining states of the Atlantic and Gulf coast. The group of states lying wholly or principally east of the 95th meridian *and not included in the first three groups* have been designated the Interior and Lake states. A fifth group comprises the remaining states and territories with the exception of California, which, on account of the very high death rate of a portion of the state, is assigned a position as a distinct region by itself.

Dr Carl Schroder writes, under date of December 4, 1884

> In my opinion, withdrawal from practice is not necessary, but can be resumed after a thorough cleansing

Prof Nussbaum writes from Munich, November 8, 1884

> I have very often made ovariotomies with the best results, the day after a post mortem, but I have always made a thorough disinfection of my hands, and changed my clothes
>
> GEHEIMRATH VON NUSSBAUM

At the beginning of this paper, I referred to the noteworthy publication of Prof Volkmann in the *Centralblatt fur Chirurgie* of 1880 In his letter to me, dated Halle, December 5, 1884, he says

> I hold the same views to day as at that time A surgeon who *disinfects* himself *well*, can immediately after making a post mortem examination, or dressing a septic wound, undertake a laparotomy, do a trepanning, examine a patient with a fresh complicating fever, or dress a penetrating wound of the joint Every morning from six to eight, during the summer, I am obliged to give the students operations on the cadaver, and from ten to three, I am busy in the Hospital operating and dressing wounds, and I have never yet infected a patient In the winter, I have no operations on the cadaver to make Comparing my results in the clinic, I can assure you, that the mortality in summer is not greater than in winter
>
> RICHARD VOLKMANN

In conclusion I present the following characteristic reply, which epitomizes the subject under discussion

> If you have *thoroughly* disinfected yourself, you can immediately enter upon obstetric practice *Time* does not destroy septic dirt
>

GEOGRAPHICAL PATHOLOGY OF CONSUMPTION[1]

BY G W McCASKEY, A M, M D,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST FT WAYNE COLLEGE OF MEDICINE FT WAYNE IND

I

The deaths from consumption in the United States, in the year 1880, numbered 91,551, almost one-eighth the entire mortality from all causes This pregnant fact seems to furnish at once an incentive and excuse for the following endeavor to ascertain what definite relation there is, if any such exists, between this disease and certain climatic conditions in the United States

An obstacle is encountered at the very threshold of the inquiry in our defective system of registration It must be admitted, in the first place, that many cases reported as consumption have no relation to that disease It is also well known that many cases are not reported at all The migratory character of a considerable body of the population—especially its westward flow—is also a disturbing element in a statistical study And, finally, those regions, the climates of which have secured the reputation of being curative of consumption, have their death-rate from this disease greatly increased by the immigration of a large number of the rapidly fatal type of cases The last-named source of error can not be removed, as there are no available records of its extent It is only found, however, in a small number of localities, and if it could be entirely removed the only effect, so far as the present study is concerned, would be to increase the force of the conclusions drawn After recognizing its existence, therefore, it may safely be dismissed

So far as the other sources of error are concerned, while their existence is to be deplored, they will not impair deductions made from data which need only be comparatively correct Indeed, for purposes of comparison the absolute death-rate is quite unnecessary The death rates of different localities might just as well be expressed in units, taking as an arbitrary standard either the highest or lowest death-rate found in any given locality, the mean death rate between these two extremes, or the average of all There is little doubt that the census report gives data which are at least relatively correct, and which can therefore be relied upon for the purposes of a comparative study The area of the United States is too vast and complicated for detailed analysis within the intended scope of this paper By a general survey, however, certain broad facts may be collated, and certain inferences drawn, which may not be without value

A basis for comparison, at once practical and scientific, is readily formed by placing side by side (1), the mortality from consumption, (2), the mortality from all causes, and (3), the percentage of the former to the latter These data will be ascertained for the United States, for groups of States, for individual States, and, in some instances, for parts of States. Notwithstanding the wide variations found in different parts of these extensive regions, each has its average of annual rain fall, of elevation, of mean annual temperature, and the like, which, taken together, or perhaps singly, are entirely characteristic of itself These distinctions are broad enough to completely overshadow local anomalies, even if these did not, in accordance with a well recognized law correct one another by mutual antagonisms

With the exception of four states (California, Florida, Louisiana and Pennsylvania) and three territories (Arizona Nevada and Montana), the death-rate from all causes was larger in 1880 than in 1870 The result of this increase upon the part of the individual states is to raise the death-rate of the United States from 13 3 per 1,000 in 1870 to 15 1 in 1880, an increase of 13½ per cent Curiously contrasting with this fact, the death rate from consumption either shows no change or a slight increase in all except fifteen of the states and territories The average for the United States, which shows no change whatever, remaining 1.8 per 1,000 for each year, only illustrates and confirms the remark that the local variations neutralize one another, thus making no change in the general result

West Virginia	9.1	11.9	1.6	1.6	17.6	13.1
Wisconsin	9.4	12.1	1.2	1.3	13.2	10.5
Wyoming	8.1	9.1	.4	.3	5.4	2.6

The well known prevalence of the disease in New England, and its rarity in the south Atlantic and Gulf coast states, becomes at once apparent. It is also observed that, with numerous undulations, it is somewhat evenly distributed over the remaining states east of the 95th meridian. In the vast region west of this meridian, comprising more than one-half the territory of the United States, and about one-fifteenth of its population, it is, with the exception of a portion of California (Texas is included in another division), even less prevalent than in the south Atlantic and Gulf coast states.

The division into groups indicated by the following table is intended to throw together adjacent states which have something in common regarding their consumption death-rate, with the view of studying some of their more important climatic conditions for the purpose above mentioned. The boundary line between these different regions, to be absolutely correct, would often, or perhaps generally, intersect the different border states. The difficulties in the way of securing statistical data for parts of states were so great, however, as to render such a division impracticable. The number of these groups, furthermore, could have been indefinitely increased, often comprising a few counties instead of several states. This could only have led to confusion, and been utterly barren of results.

TABLE II.

Showing death rate (1) from all causes, (2) from consumption, and (3) percentage of latter to former in groups of States.[1]

	Deaths per 1000 of Population from all causes		Deaths per 1000 of Population from Consumption		Percentage of Deaths from Cons'n to Deaths fr. all causes	
	1870	1880	1870	1880	1870	1880
New England States	14.6	16.7	3.0	2.6	20.8	16.1
Middle States	14.9	16.2	[illegible].4	2.2	15.8	13.8
S. Atlantic and Gulf States	12.2	14.6	1.0	1.3	8.1	8.8
Interior and Lake States	11.5	14.6	1.6	1.8	14.2	12.0
States and Territories W. of 95th Meridian except Texas and California	10.8	13.8	0.9	1.0	8.5	7.1
California	16.1	13.4	2.2	2.2	13.8	15.6

Having marked out the different regions for individual study, and noted the high mortality from consumption in the New England and Middle states, and the low mortality in the south Atlantic and Gulf states, and the western half of the continent, it now remains to study the climatic conditions of each group in their bearings upon this disease.

Temperature.—Temperature may first be considered, as one of the most prominent factors in that combination of conditions called "climate." The mean annual temperature will be taken as the standard of comparison. In making estimates of the mean annual temperature of a group of states, it should be constantly born in mind, that they are only the averages of more or less widely diverging extremes. The same caution is necessary in considering the like estimates of annual rain fall, and altitude which are to follow. As absolute measurements, they are not reliable, as comparative statements—and it is for purposes of comparison only that they are introduced—they are believed to be approximately correct. A glance at the isothermal, isohyetal, and hypsometric charts, especially the first two, will illustrate in a very forcible manner, the difficulties encountered. Taking the entire Atlantic and Gulf Coast line, we find a very marked decrease in its consumption death rate as the mean annual temperature rises This is shown in a general way by the individual states, but more distinctly by comparing the groups into which these states have been divided for the purpose of this inquiry Commencing with the New England States, we find a mean annual temperature of 40 to 48 degrees Fahr, with a consumption death rate of 2 6 to 3 0 per thousand of the population, or 16 1 to 20 8 per cent of all deaths Passing down to the Middle States, we find that the mean annual temperature rises about four degrees—44 to 52 degrees Fahr, the consumption death rate falling to from 2 2 to 2 4 per thousand, or 13 8 to 15 8 per cent of the deaths from all causes This change is not due to any decrease in the general mortality, for this remains practically the same as in the New England States, being 3 greater in 1870, and 5 less in 1880 Still farther down (South Atlantic States), the mean annual temperature rises to from 60 to 76 degrees Fahr, and the consumption death-rate falls to from 1 to 1 3 per one thousand, or 8 1 to 8 8 per cent of all deaths Here again the decrease in the consumption death rate is out of all proportion to the decrease in the general death-rate—the former being 41 and the latter 10 per cent Southern Louisiana presents a notable departure from this average, by showing a very large mortality from consumption

---

[1] The New England and Middle states were assigned positions as separate groups partly because of their long recognized geographical unity and partly because there were no apparent reasons for uniting the two groups or subdividing either. The third group includes the remaining states of the Atlantic and Gulf coast. The group of states lying wholly or principally east of the 95th meridian *and not included in the first three groups* have been designated the "Interior and Lake states." A fifth group comprises the remaining states and territories with the exception of California which on account of the very high death rate of a portion of the state is assigned a position as a distinct region by itself.

On the contrary, when we compare the Interior and Lake states as far west as Kansas and Nebraska in different latitudes under the same meridian, we find a general increase in the consumption death rate as we pass from North to South Taking the states traversed by the 85th meridian, the death rates per one thousand of the population for 1880, were as follows Michigan, 1 6, Indiana, 2 0, (Ohio by its side 1 9), Kentucky, 2 3, and Tennessee 2 5 In 1870, however, no difference was reported between Kentucky and Tennessee Again, taking the states traversed by the 94th meridian, the death-rates are as follows Minnesota, 1 1, Iowa, 1 2, Missouri, 1 7, but here the rise ceases, and Arkansas falls to 1 2 while its mean annual temperature is about 20 degrees Fahr higher than that of Minnesota On the 100th meridian it is as follows Dakota, 8, Nebraska, 9, and Kansas 1 1, thus showing a slight gradual increase with the rise of temperature But the relative positions of Dakota and Nebraska in the scale, were reversed in 1870, while Arizona and New Mexico, with about the same temperature as Tennessee, have about the lowest death-rate in the United States, while Tennessee has nearly the highest Southern California, with a mean annual temperature considerably higher than the northern portion of the state, is almost exempt from the disease, while it is very prevalent in the latter portion of the state Oregon and Washington Territory with a temperature more than 20 degrees lower than that of Arizona, have a mortality from consumption more than three times as great

What, then, are the inferences to be drawn from these facts, regarding the etiological relation of different mean annual temperatures to consumption as indicated by its mortality? From the Atlantic coast alone we are justified in concluding that consumption diminishes, almost *pari passu*, with a rise of temperature This is rather the statement of a fact than an inference But, on the other hand, that temperature alone is either unimportant or entirely masked by other conditions, is abundantly shown The same isothermal belt, for instance, traverses Maine and Minnesota, the consumption death-rate in the latter being about one-third that of the former That the difference is not dependent upon the general healthfulness of Minnesota is conclusively proven by the fact that its death rate from all causes is three fourths that of Maine The question of temperature is almost inextricably complicated with other atmospheric conditions of scarcely less importance But in the face of the foregoing facts, the view that low temperatures protect from phthisis, while high temperatures favor its development, is clearly untenable The facts obtained both from the Atlantic and Pacific coasts clearly point in exactly the opposite direction, and it ought certainly to be anticipated that repeated congestions, which low temperatures so commonly produce, will aggravate the disease, and make it run a much more rapid course Not only so, but in many instances the disease apparently has its origin in such a congestion of the bronchial mucous membrane, called a "cold" Whether a specific poison is essential or not, without the "cold" the consumption would probably not have developed

The view that a warm climate is the one in which consumptive patients will thrive the best, and those not consumptive be least likely to become so, seems equally, if not more rational upon *a priori* grounds It is, moreover, quite as well sustained by a study of the facts already presented It must be confessed, however, that neither view can be established by evidence derived from this source So conflicting is this evidence, that one feels little surprise at the therapeutical antithesis enunciated in a recent monograph, viz that extreme heat and cold are perhaps equally efficacious in cutting short the disease[1]

But for the consumptive patient seeking a climate where he may live the longest and live the best, it would seem wiser to go where the vessels of the skin were least liable to be constricted by external cold, with the necessary sequence of determination of blood to internal organs One such occurrence may produce irreparable, and perhaps rapidly fatal mischief Fortunately, the false and pernicious doctrine that consumption is incurable has been completely overthrown The question is, therefore not always between a rapid and a lingering death, but often between death and partial or complete recovery, which may be either temporary or permanent, the very possibility of which makes the subject of treatment so much the more grave and important

The frequency and extent of sudden changes of temperature will be passed without discussion, because of insufficient data, and the fear of extending too far the limits of this paper

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

Clinical and Physiological Investigations on Paraldehyde —Dr Vincent Cervello gives the result of his experiments with this drug in the *Archives Italiennes de Biologie*, Tome VI, Fasc 2, as made upon himself and his assistants The drug was taken in the early morning, when fasting, and three to four hours after breakfast or dinner The dose varied from 1 to 3 grammes in aqueous solution The absorption of paraldehyde through the alimentary canal he found to be very rapid, only five minutes being necessary to produce its general effect, and in five minutes more sleep was often produced Absorption took place with similar rapidity by the rectum, hypodermically it was delayed somewhat The character of the sleep produced was strictly physiological the awakening was natural—no malaise, or pain in the head and the subjects returned readily to their ordinary occupations, except that when taken in the morning on the evening of the same day unusual sleepiness occurred early The sleep was profound for fifteen minutes to an hour, and then a gradual diminution until awake When kept awake after taking a dose the somnolent feeling remained for an hour and a half or three quarters The radial pulse remains normal in amplitude, diminishing about four beats per minute, except in the profound sleep, when it is reduced six to ten beats per minute Bergesio and Mosso have studied in the brain of an individual who, having had a portion of the temporal bone resected for the extirpation of a sarcoma, a cicatrix remained in the antero superior portion of the left temporal fossa, by means of which Mosso's method could be used to show the effects on the cerebral pulse during sleep of paraldehyde, morphia and alcohol With paraldehyde, the volume of the brain diminished and the blood pressure in the organ was lowered Respiration was not modified when awake, when asleep the number of respirations diminished one or two per minute, and became also somewhat less ample The temperature remained at normal while awake, lowering a few tenths during sleep Healthy persons suffer no derangement of the alimentary canal from its prolonged use, no loss of appetite The absorption of paraldehyde is too rapid to permit of its decomposition into aldehyde in the stomach, which is the view held by Limousin Its principal elimination is by the pulmonary surface, —the expired air having a peculiar odor, the urine also carries a similar odor

Dr Cervello regards this agent as useful as a hypnotic, as a sedative, and as an antagonist to strychnia poisoning, and to diseases the symptoms of which resemble the latter, and he gives cases to support his views He advises its use especially in affections of the heart where chloral is absolutely contra indicated, giving one case of hypertrophy with myocardial degeneration, mitral stenosis and insufficiency of the aortic semilunar valves, where great relief was given He calls it a true heart tonic Careful examinations of cases of albuminuria show in some no alteration, in others a diminution of the amount of albumen, as indicating in the latter an amelioration of the general condition

The counter indications for its use seem, to be reduced to the minimum by Dr Cervello, but ulcerations in the stomach are affected unfavorably by it, nor is it well supported in the last stages of pulmonary phthisis with ulcerations of the larynx, in the case of a child he was obliged to stop its use from the excitable cough, due perhaps to direct irritation of the ulcerated mucous membrane

As to the dose, 3 grammes furnishes the medium amount, but there are many individuals who are susceptible to 1 gramme or even less He does not find that patients become readily accustomed to its effects, so as to require increased doses When given, the paraldehyde must be diluted, as it produces a burning sensation in the mouth Guyl has given it hypodermically, and finds that it produces a brisk irritation not lasting, nor followed by any inflammatory reaction, the hypnotic effect was moderate, even after the injection of 3 grammes Cervello has only used it on animals in this way, and they seemed to suffer considerably The paraldehyde of commerce is often impure by containing acetal, which renders it disagreeable and less active, and valeric aldehyde, which has a poisonous action

The Oil of Eucalyptus in Typhoid Fever —Dr Leighton Kesteven has been using this drug in the Brisbane General Hospital, and speaks highly (*Practitioner*, May, 1885) of its effects He used it as a germicide in an epidemic of typhoid fever, giving ten minims made up into an emulsion with mucilage every four hours In about eighteen months he attended 220 cases of typhoid, with but four deaths, and of these there was in every case an unfavorable circumstance Without being absolutely nauseous, this medicine does not agree well with all stomachs, but this difficulty can be entirely overcome by careful emulsification, and the addition of half a drachm each of aromotic spirits af ammonia, spirits of chloroform, and glycerine, the latter entirely removing the rough semi resinous taste of the oil The effects of this medicine are, in brief, as follows

1 It steadily and permanently reduces the force and frequency of the pulse In one case the pulse, from being a sledge hammer pulse of 120, went to 90 within an hour of the first dose of the medicine, and never went above 90 again

2 Lowering of the temperature This occurs less rapidly, and might be entirely secondary to, and dependent on, the lowering of the pulse

3 The beneficial effect on the tongue is very marked, almost immediately alleviating the distressing dryness so universal in typhoid, and removing the thick brown coating, leaving but proportionately little fur, and frequently clearing the tongue entirely in a very short time

4 The skin, along with the reduction in its temperature, becomes moist and soft, in contrast with the harsh, dry, hot skin so frequent and persistent, conferring a corresponding increase of comfort to the sufferer

is particularly the case when the interval of time is 10 years and longer

2 Persistent vomiting manifests itself more frequently after a long interval than after a short one

3 There is less liability to ante-partum hæmorrhage

4 There is a relative or absolute increase in the liquor amnii

5 The duration of labor is greater, and relates particularly to the first period, the other two being but little modified If the interval be more than 10 years, the duration of the third period is increased, and labor appears to be as long, or even longer, than with primaparæ

6 The duration of labor with biparæ is about 10½ hours

7 In cases of long interval feebleness of contractraction is more marked Lacerations of the perinæum are more frequent, as also post partum hæmorrhages, adhesions of the placenta, diseases of the kidneys, and increase in frequency of œdema of the extremities without albuminuria

8 Inflammations of the breast diminish with the length of interval, as well as the amount of milk

9 Morbidity and puerperal mortality increase

10 Puerperal mania does not seem to be increased

11 The longer the interval, especially after 10 years, the less prospect is there for the pregnancy to reach full term The length of the interval has no sensible influence on the frequency of normal or abnormal presentations of the fœtus It favors the birth of girls rather than boys The child is larger and longer The shorter the interval the greater the disposition to prolapsed funis Twin pregnancies increase with the interval, as also fœtal malformations

12 The longer the interval the greater the fœtal mortality This is applicable to still births, to children dying immediately after delivery, and to those who die in the eight days after delivery —*Archives de Tocologie*, May, 1885

FACE AND BROW PRESENTATIONS —DRS BEUMER and PEIPER contribute to the *Archiv fur Gynäkologie* (Band xxiii, Heft 1), an account of the midwifery clinic at Griefswald, under Professor Penn
the last 25 years The most interesting
instalment given is that which relates to th
face and brow presentation observed (1)
sentations —The births in this clinic in 25 yea
bered 6,336, and among these occurred 54 ca
face presentations, a proportion rather above
average The authors consider in the light of the
cases, some of the causes o
these presentations First,
theory, that they are due to r
fœtus, producing extension of t
grasped by the wall of the uteru
pelvic inlet, a theory in accordanc
asserts that face presentations cann
centa prævia, nor with a dead fœtu
tions are negatived in the paper befc
record of cases in one of which face
occurred with placenta prævia, and in th
a decomposing fœtus The authors nex

the dependence of face presentation upon pelvic contraction, a condition said by Winckel to be present in rather more than a fifth of all face presentations Our authors, out of 54 face cases, find contracted pelvis present in only 4 They therefore agree with Hecker, in thinking pelvic contraction only an infrequent cause of this presentation Hecker's theory, that it is often due to a dolicho cephalic head, is the next subject for discussion It is, as every one knows, common for children born after face presentations to have heads longer than common, but this is mainly due to compression during labor Drs Beumer and Peiper nevertheless think that in some cases face presentation may be due to peculiarities in the shape of the head, either greater length, or unusual width in the biparietal measurement They refer to cases published by Fritsch in which not only was the biparietal measurement unusually large at the time of birth, but in the first few days of life still further increased, this latter fact proving that the increase was not produced by pressure during labor Out of the 54 cases in the Griefswald clinic, in 6 the head was unusually large, and in two there was hydrocephalus Our authors give three cases in which face presentation was primary, that is present before the beginning of labor In one it was present 5 days, in another 10 days, and in another 8 days, before the commencement of the pains The infantile mortality was 6 out of 54 In 5 cases forceps were used, 7 times delivery was effected by turning, twice by perforation, and in one case the "accouchement force" was resorted to, with a fatal result to the mother The special therapeutical measure which the authors favor in the most difficult cases, viz those with the chin posterior, is the rotation of the chin forward with the forceps This was attempted in two of the cases, in one with success, in the other without, perforation being then necessary

(2) *Brow presentations* —Of these no less than 9 occurred out of the 6,336 cases Six of the children were still-born, and three of the mothers died, another of them being left with a vesical fistula, facts which sufficiently show the difficulty of labor with the head presenting in this position In three cases,
lab minated by the natural efforts, in two of
assing through the pelvis in the brow
r the brow presentation being
in vertex Three were

absolute extinction of the voice of several days' standing was completely restored by one application of the heated points.

CONSERVATIVE SURGERY IN ARTICULAR TUBERCULOSIS.—M. OLLIER (*Revue de Chirurgie*), terminates his remarkable work upon direct interference in articular tuberculosis with the following series of conclusions:

1. The chronic osteo-arthrites which we group to-day under the name of articular tuberculosis, present numerous clinical varieties which require different modes of treatment. Some are curable by the abrasion or destruction, locally, of the tuberculous products without sacrifice of the surrounding healthy bone tissue; others require the ablation of the bony extremity which is the seat of the disease, that is to say, a typical resection; others again must be treated by amputation of the limb.

2. Whatever may be the views of to-day upon the infectious nature of tuberculosis, what is, or appears to be local tuberculosis in man, is noted from its resting indefinitely restricted to its original seat and with little tendency to generalise. All cases of articular caries are not tuberculous, but the greater
part are closely related to that form of disease. The
ogress of tuberculosis is very variable, according
the subject. The question of individual consti-
very important one, the same germ devel-
rting, according to its field for culture.

f conjugation. Am
necessary in middle
eat difference in the
racter of the artic-
gress of the tuber-

e as possible should
plied to the gener-
a leads to most de-

plorable therapeutic errors. Among the conservative operations, arthrotomy, abrasion, gouging, and tunneling of the bone, which give such good results in children, should not be undertaken with the adult except with great reserve. When lesions that are manifestly tubercular are to be dealt with, the whole of the bony extremity must be removed to obtain a rapid and complete cure.

7. In spite of antisepsis, the economical operations on the bony tissues are graver in the large articulations than the typical resections, and they are less efficacious. Uncertain in their results, on account of the possible diffusion of the tuberculous focus, they are always open to the fear of a local relapse, they expose the cases to a generalization of the tuberculosis, not only more than amputation, but more than the typical resection, which removes the habitual seat of the tubercular foci and extends beyond their limits.

8. The rule of removing all of the tubercular products does not implicate the supporting tissues which only present the lesions of chronic inflammation. In removing the totality of the fibrous articular tissues, there results from the resection very defective orthopædic and functional changes. These tissues must be preserved and modified ulteriorly, if they become fungous. Therefore an immediate reunion of the parts after resection in tubercular osteo arthritis, is not desirable; there must be reserved a means of modifying or destroying the fungous granulations which may re-form.

9. Amputation is undoubtedly the operation most likely to put secondary infections out of the question; but it cannot be considered as a radical operation, on account of the persistence of the deeper and inaccessible glands which are always more or less involved in the older lesions. It is particularly indicated in osteo arthritis of the lower extremities, for it is important to sustain promptly the patient against the alterations of nutrition which result from prolonged inaction and lying in bed.

10. When an articular resection has been followed by a local cure, which is complete and permanent, and a stable cicatricial tissue has replaced the fungous tissue, the patient is no more exposed than after an amputation to the invasion of the internal organs. This permanence of the local cure, whilst the internal organs might become invaded, is the great argument in favor of resection. The patient has preserved his limb, and finds himself in as favorable a condition as after an amputation, so far as secondary infection is concerned.—*Journ. de Médecine de Paris*, May, 1885.

OBSTETRICS AND GYNÆCOLOGY

THE INFLUENCE ON LABOR OF THE INTERVAL BETWEEN FIRST AND SECOND LABORS.—LUDWIG KLEINWAECHTER (*Zeitsch. f. Geb. u. Gynak.*, I. XI, cap. I), gives the following:

1. Women who become pregnant for the second time, after a long interval of time (6 to 16 years), become subject to sickness, whether accidental or dependent upon pregnancy, much more readily than those who conceive more rapidly (1 to 6 years), this

Tamponing the Nasal Fossæ with Plugs Soaked in Turpentine.—Dr. L. Bodeir, in the *Jour. de Med. et de Chir. Pratique* for May, 1885, praises this as a simple and efficacious process, which he has often employed to arrest nasal hæmorrhage. This method occurred to him after a case in which he had used Belloc's sound and plugged the nares so effectually that for ten days the blood, not being able to escape anteriorly or posteriorly, welled up through the lachrymal canals, two little streams of blood running down the cheeks for about eight days. The case was one affected with slight fever, but resulted in the formation of petechiæ, intestinal hæmorrhage and death. Comprehending from this that tamponing alone would not suffice, and satisfied of the insufficiency of perchloride of iron, he made a tampon of small balls of wadding attached to each other by a string like the tail of a kite (in other words, the old classic vaginal tampon), soaked the balls in turpentine, squeezed them afterwards, and filled the anterior nasal fossæ with them, without regard to the posterior fossæ, which remained open. The heat causes a part of the turpentine to vaporize, and the most inaccessible folds of the fossæ come under its irritating influence, and by this means he has treated successfully twenty or more cases under diverse circumstances.

Hygrine or Cocaine.—Cocaine, the wonderful drug which anæsthetizes mucous membranes, and has simplified many minor operations on the eye, is very costly. Hence we must not be surprised to hear that, in Paris at all events, the manufacturers endeavor to obtain as much of the alkaloid as possible by submitting the coca leaves to a second process of exhaustion. The result is very similar to that which follows attempts to make a second infusion out of already exhausted tea leaves. Certain substances are extracted which are not cocaine, but have nevertheless a remarkable effect on the pupil, causing it to dilate in a marked manner. These substances are derivatives of hygrine, most of which are mydriatics. Eserine is not an efficient antagonist to atropine, but it is to these derivatives of hygrine. Our readers may have observed that different observers have made different statements with regard to the action of cocaine on the pupil. Some have asserted that cocaine has a powerful mydriatic effect, which others have not noticed. This difference may be explained by the above mentioned facts.—*Lancet*, May 16, 1885.

Glycerine as a Tænicide.—Dr. G. A. McCallum, of Dunville, Ontario, writes to the *British Medical Journal*, of June 13, that glycerine is the most efficient tænicide that he has yet seen. In some cases it may be necessary to follow the glycerine with a gentle purgative. He has found that when the head of the worm is placed in glycerine, it dies almost immediately. This fact is especially important in treating cases of tænia in children.

MEDICINE

Lead-Poisoning in Infants.—Dr. J. Lowey reports three cases of lead poisoning occurring in infants which deserve to be widely promulgated, especially among the laity, to avoid the causes leading to the intoxication.

1. A child of five weeks of age, nourished by a wet-nurse, was suddenly seized with violent colicky paroxysms, accompanied by a bluish color of the skin. The cause was found to be the lead containing face powder of the child's nurse.

2. Another infant of the same age showed similar symptoms, which were traced to the use of lotions of Goulard's extract by its nurse, which she applied to her sore breast, without cleaning the latter thoroughly before nursing her child.

3. An infant of three months of age was taken suddenly ill with distinct symptoms of lead-poisoning. An examination revealed that the nursing bottle used by the infant contained a lead cork, and that on account of a rupture in the rubber tube passing through this metal cork the lead came in direct contact with the milk.—*Wiener Medizinische Presse*, xxiv. 49; *Therapeutic Gazette*, May, 1885.

SURGERY

A New Treatment for Goitre.—The new treatment used by Dr. A. Weiss (*Berlin Klin. Wochenschrift*, No. 2, 1885), is the application of heated points to the surface of the tumor. By means of a Paquelin apparatus with a pointed iron, he makes punctures about one centimetre apart, the iron being at a white heat. The burns result in little scabs of one to three millimetres, which fall off in a few days, leaving behind them cicatrices which are at first red and then white. If the iron is at a white heat there is but little pain produced, and the consecutive treatment consists simply in covering the wound with a layer of wadding. The operation is repeated every six or eight days until the disappearance of the goitre, which requires, according to circumstances, from six to twelve applications. At the same time a little iodide of potassium is given, but this is not essential. This treatment is particularly beneficial in endemic parenchymatous goitre, in cystic goitre it is not so much so. Sometimes during treatment the goitre ceases to diminish; he then applies, immediately after the operation, a layer of vaseline over the burns; in this way suppuration is set up under the scabs, which hastens the cure. In explaining the curative action Dr. Weiss considers that the heated points provoke an excitation of the terminal nerve filaments, which causes a contraction of the muscular coat of the vessels, resulting in an arrest of nutrition and atrophy of the hypertrophied glandular substance. In one case where the goitre was so covered by a network of large vessels that Prof. Luke could not administer an injection of iodine or arsenic, Weiss observed, after four or five applications of the heated points, a diminution in the calibre of these same vessels, which became normal. In this same case he applied the heated points to a greatly dilated vein in the axilla, and the next day noted a diminution in its volume. He is inclined to use this treatment in other affections, as catarrh, affections of the pleura. In one case of laryngo tracheal catarrh, an absolute extinction of the voice of several days' standing was completely restored by one application of the heated points.

Conservative Surgery in Articular Tuberculosis.—M. Ollier (*Revue de Chirurgie*), terminates his remarkable work upon direct interference in articular tuberculosis with the following series of conclusions:

1. The chronic osteo-arthrites which we group to-day under the name of articular tuberculosis, present numerous clinical varieties which require different modes of treatment. Some are curable by the abrasion or destruction, locally, of the tuberculous products without sacrifice of the surrounding healthy bone tissue; others require the ablation of the bony extremity which is the seat of the disease, that is to say, a typical resection; others again must be treated by amputation of the limb.

2. Whatever may be the views of to-day upon the infectious nature of tuberculósis, what is, or appears to be local tuberculosis in man, is noted from its resting indefinitely restricted to its original seat and with little tendency to generalise. All cases of articular caries are not tuberculous, but the greater part are closely related to that form of disease. The progress of tuberculosis is very variable, according to the subject. The question of individual constitution is a very important one, the same germ developing or aborting, according to its field for culture.

3. It is in the local tuberculosis and in all the circumscribed suppurative lesions, whatever may be their cause, that conservative operations on the limbs and economical operations on the bony tissue are particularly indicated. We are guided in our choice of operation, according to the extent and seat of the lesions, and with the purpose of removing as completely as possible a focus which might become at any time the point of departure for secondary infection by the migration of new colonies of bacteria or other infectious germs.

4. A spontaneous cure of osseous and articular tuberculosis is often observed in infancy and adolescence; it acts by elimination or transformation of the morbid products. In removing by surgical means the tubercular products, we follow the method indicated to us by nature when she cures these affections by spontaneous elimination. With the adult, the spontaneous cure of tubercular osteo-arthritis is much rarer, the coexisting visceral lesions are more frequent and the generalization more menacing.

5. It is in infancy and childhood that these various conservative operations are especially indicated; with the child typical resections are performed by preference, operations which will not interfere with the growth of bone by the cartilage of conjugation. Amputations are more frequently necessary in middle life and old age; but there is a great difference in the indications, according to the character of the articulation itself and the clinical progress of the tuberculosis.

6. The idea of removing as little as possible should always guide the surgeon; but applied to the generality of tubercular lesions this idea leads to most deplorable therapeutic errors. Among the conservative operations, arthrotomy, abrasion, gouging, and tunneling of the bone, which give such good results in children, should not be undertaken with the adult except with great reserve. When lesions that are manifestly tubercular are to be dealt with, the whole of the bony extremity must be removed to obtain a rapid and complete cure.

7. In spite of antisepsis, the economical operations on the bony tissues are graver in the large articulations than the typical resections, and they are less efficacious. Uncertain in their results, on account of the possible diffusion of the tuberculous focus, they are always open to the fear of a local relapse, they expose the cases to a generalization of the tuberculosis, not only more than amputation, but more than the typical resection, which removes the habitual seat of the tubercular foci and extends beyond their limits.

8. The rule of removing all of the tubercular products does not implicate the supporting tissues which only present the lesions of chronic inflammation. In removing the totality of the fibrous articular tissues, there results from the resection very defective orthopedic and functional changes. These tissues must be preserved and modified ulteriorly, if they become fungous. Therefore an immediate reunion of the parts after resection in tubercular osteo-arthritis, is not desirable; there must be reserved a means of modifying or destroying the fungous granulations which may re-form.

9. Amputation is undoubtedly the operation most likely to put secondary infections out of the question; but it cannot be considered as a radical operation, on account of the persistence of the deeper and inaccessible glands which are always more or less involved in the older lesions. It is particularly indicated in osteo-arthritis of the lower extremities; for it is important to sustain promptly the patient against the alterations of nutrition which result from prolonged inaction and lying in bed.

10. When an articular resection has been followed by a local cure, which is complete and permanent, and a stable cicatricial tissue has replaced the fungous tissue, the patient is no more exposed than after an amputation to the invasion of the internal organs. This permanence of the local cure, whilst the internal organs might become invaded, is the great argument in favor of resection. The patient has preserved his limb, and finds himself in as favorable a condition as after an amputation, so far as secondary infection is concerned.—*Jour. de Medecine de Paris*, May, 1885.

OBSTETRICS AND GYNÆCOLOGY

The Influence on Labor of the Interval Between First and Second Labors.—Ludwig Kleinwaechter (*Zeitsch. f. Geb. u. Gynak.*, T. XI, cap. I), gives the following:

1. Women who become pregnant for the second time, after a long interval of time (6 to 16 years), become subject to sickness, whether accidental or dependent upon pregnancy, much more readily than those who conceive more rapidly (1 to 6 years), this

is particularly the case when the interval of time is 10 years and longer

2 Persistent vomiting manifests itself more frequently after a long interval than after a short one

3 There is less liability to ante-partum hæmorrhage

4 There is a relative or absolute increase in the liquor amnii

5 The duration of labor is greater, and relates particularly to the first period, the other two being but little modified If the interval be more than 10 years, the duration of the third period is increased, and labor appears to be as long, or even longer, than with primiparæ

6 The duration of labor with bipara is about 10½ hours

7 In cases of long interval feebleness of contraction is more marked Lacerations of the perinæum are more frequent, as also post-partum hæmorrhages, adhesions of the placenta diseases of the kidneys, and increase in frequency of œdema of the extremities without albuminuria

8 Inflammations of the breast diminish with the length of interval, as well as the amount of milk

9 Morbidity and puerperal mortality increase

10 Puerperal mania does not seem to be increased

11 The longer the interval, especially after 10 years, the less prospect is there for the pregnancy to reach full term The length of the interval has no sensible influence on the frequency of normal or abnormal presentations of the fœtus It favors the birth of girls rather than boys The child is larger and longer The shorter the interval the greater the disposition to prolapsed funis Twin pregnancies increase with the interval, as also fœtal malformations

12 The longer the interval the greater the fœtal mortality This is applicable to still births, to children dying immediately after delivery and to those who die in the eight days after delivery —*Archives de Tocologie*, May, 1885

FACE AND BROW PRESENTATIONS —DRS BEUMER and PEIPER contribute to the *Archiv fur Gynakologie* (Band xxiii, Heft 1) an account of the midwifery clinic at Griefswald, under Professor Pennice, during the last 25 years The most interesting part of the instalment given is that which relates to the cases of face and brow presentation observed (1) *Face presentations* —The births in this clinic in 25 years numbered 6,336, and among these occurred 54 cases of face presentations, a proportion rather above the average The authors consider, in the light of these cases, some of the causes commonly assigned for these presentations First, they consider Braun's theory, that they are due to reflex movements of the fœtus, producing extension of the chin, which is then grasped by the wall of the uterus, and so fixed in the pelvic inlet, a theory in accordance with which Braun asserts that face presentations cannot occur with placenta prævia, nor with a dead fœtus These assertions are negatived in the paper before us, by the record of cases in one of which face presentation occurred with placenta prævia, and in the other with a decomposing fœtus The authors next consider the dependence of face presentation upon pelvic contraction, a condition said by Winckel to be present in rather more than a fifth of all face presentations Our authors, out of 54 face cases, find contracted pelvis present in only 4 They therefore agree with Hecker, in thinking pelvic contraction only an infrequent cause of this presentation Hecker's theory, that it is often due to a dolicho cephalic head, is the next subject for discussion It is, as every one knows, common for children born after face presentations to have heads longer than common, but this is mainly due to compression during labor Drs Beumer and Peiper nevertheless think that in some cases face presentation may be due to peculiarities in the shape of the head either greater length, or unusual width in the biparietal measurement They refer to cases published by Fritsch in which not only was the biparietal measurement unusually large at the time of birth but in the first few days of life still further increased, this latter fact proving that the increase was not produced by pressure during labor Out of the 54 cases in the Griefswald clinic, in 6 the head was unusually large, and in two there was hydrocephalus Our authors give three cases in which face presentation was primary that is, present before the beginning of labor In one it was present 5 days, in another 10 days and in another 8 days, before the commencement of the pains The infantile mortality was 6 out of 54 In 5 cases forceps were used, 7 times delivery was effected by turning, twice by perforation and in one case the "accouchement force" was resorted to, with a fatal result to the mother The special therapeutical measure which the authors favor in the most difficult cases viz those with the chin posterior, is the rotation of the chin forward with the forceps This was attempted in two of the cases, in one with success, in the other without, perforation being then necessary

(2) *Brow presentations* —Of these no less than 9 occurred out of the 6,336 cases Six of the children were still born, and three of the mothers died, another of them being left with a vesical fistula, facts which sufficiently show the difficulty of labor with the head presenting in this position In three cases, labor was terminated by the natural efforts in two of them the head passing through the pelvis in the brow position, in the other the brow presentation being spontaneously converted into a vertex Three were delivered by forceps, two by turning, and one by perforation The authors remark upon the paucity of information given in most text-books upon these extremely difficult cases They recommend that, if brow presentation is early recognized, turning should be performed If not seen until too late for turning, *i e*, when the liquor amnii has escaped and the uterus has contracted round the child, then they think forceps should be applied, by traction with which the malposition will sometimes be corrected Attempts at converting the brow presentation into a face or vertex, by pressure with the finger, as is advised in many books, they think almost invariably fail If by the forceps delivery is not quickly effected, then they advise perforation without further delay —*Medical Times*, May 16, 1885

SATURDAY, JULY 4, 1885

THE INTERNATIONAL MEDICAL CONGRESS OF 1887

The General Committee on the Organization of the International Medical Congress of 1887, assembled in the Palmer House, in this City, on the 24th of June, 1885, in accordance with previous notice Twenty-five of the thirty eight new members added to the Committee by the Association in New Orleans were present, while the original Committee appointed at the meeting in Washington was represonted by Drs J S Billings and I Minis Hayes Dr Austin Flint not being able to attend, sent his resignation as member of the Committee, which was accepted, and Dr J W S Gouley, of New York, was elected to fill the vacancy, making the whole number of members present twenty-eight As Dr Flint, the former President of the Committee, had ceased to be a member, a new election of officers for the permanent organization of the Committee became necessary A few ballotings resulted in the election of Dr R Beverly Cole, of San Francisco, as Chairman, Dr J S Lynch, of Baltimore, as Vice Chairman, and Dr John V Shoemaker, of Philadelphia as Secretary Drs J S Billings and A Y P Garnett, of Washington were put in nomination for the latter office, but both declined to serve The Committee having been thus organized simply as a *Committee of Arrangements* for the coming International Congress, its officers having no reference to, or connection with any offices in the Congress itself, proceeded to the important work for which it had convened A motion made by X C Scott, of Ohio, directing the Chairman of the Committee to appoint a Sub Committee of nine members to consider, and report on such revision and amendments as might be deemed necessary, of the previously adopted rules and appointments for the proposed Congress, was adopted, and the Chairman appointed the following members such Committee

X C Scott, of Ohio, J S Billings and J B Hamilton, of D C , J W S Gouley, of New York, W A Wathen, of Kentucky, John V Shoemaker of Penn , E F Upham, of Vermont, J W McLaughlin, of Texas, and D A Linthicum, of Arkansas

The General Committee adjourned until 7 30 P M , and subsequently to 9 A M , of the next day, for this Sub Committee to complete a report

On the assembling of the General Committee on the morning of the 25th, the Sub Committee presented a report, which after free discussion and some alterations was adopted We had hoped to receive from the Secretary an official copy in time for this week's issue of the JOURNAL, but in the absence of such copy it is sufficient for our present purpose to state that there was no desire manifested to make any revolutionary or radical changes in the general plan of organization previously adopted On the contrary, nearly all the general rules pertaining to the membership and the working of the Congress *both in* the general sessions and in the sections, were left unchanged Those relating to the organization of the General Committee itself were very properly so changed as to make them applicable to a Committee of Arrangements only, and not to a committe whose officers were to be nominated for election to the chief offices of the Congress The nineteen sections previously provided for were reduced to sixteen by adding obstetrics to the section of gynæcology, nervous and mental diseases to the section of medicine, and oral and dental surgery to the section of surgery The chairmen of only four of the sections were changed, namely Section 1 —Medical Education, Legislation and Registration, at the head of which was placed Dr Stanford E Chaille, of New Orleans, instead of Dr Henry P Bowditch, of Boston Section 9 —Opthalmology, to which was assigned Dr E Williams, of Cincinnati, in the place of Dr Henry D Noyes, of New York Section 13 —Laryngology, of which Dr J W Mackenzie, of Baltimore was made Chairman in place of Dr George M Lefferts, of New York, and Section 18 —Diseases of Children, of which Dr J Lewis Smith, of New York, was made Chairman instead of Dr A Jacobi of the same city The chairmen of the remaining twelve sections were left unchanged, viz for Anatomy, Dr Joseph Leidy, of Philadelphia, Physiology, Dr John C Dalton, of New York, Pathology, Dr Francis Delafield, of New York, Medicine, Dr J M Da Costa, of Philadelphia, Surgery, Dr D W Yandell, of Louisville, Obstetrics and Gynæcology, Dr Robt Battey, of Rome, Ga , Otology, Dr Clarence J Blake, of Boston, Dermatology and Syphilis, Dr Wm A Hardaway, of St Louis, Public and International Hygiene, Dr H A Johnson, of Chicago, Collective Investigation, Nomenclature and Vital Statistics, Dr N S Davis, of Chicago, Military and Naval Surgery and Medicine, Dr D L Huntington, of U S Army, Practical and Experimental Therapeutics, Dr H C Wood, of Philadelphia

By the foregoing changes, it will appear that instead of five Chairmen of Sections being centered in New York and four in Philadelphia, making within a fraction of one-half of the whole number in those two cities, the number in each of these cities is reduced to three, while the remaining ten are distributed as follows Two in Chicago, Ill , one in Cincinnati, Ohio, one in St Louis, Mo , one in Louisville, Kentucky, one in New Orleans, La, one in Rome, Ga , one in Baltimore, Md , one in Boston, Mass , and one in the Medical Corps of the U S Army When the complete record of the doings of the Committee is obtained showing the names of the Secretaries and members of the Councils of Sections, it will be found that a still more general selection has been made from all parts of the country, and yet without any lowering in the standard of the qualifications of those selected If we are correctly informed, Dr Austin Flint, Sr , was again selected for nomination as President in the Preliminary Organization of the Congress, and with the exception of one or two, the same list of Vice-Presidents as previously selected and published It will thus appear that the work of the Committee during its recent meeting, has been, as we predicted, highly conservative and for the most part judicious

So far from acting the part of "soreheads" and "outs" anxious to get themselves into official positions, as represented by certain Medical Journals, they have preserved a very large part of the work previously done, and left but one of their own number occupying any prominent official position in connection with the Congress, namely, Dr Robert Battey, of Georgia, who remains Chairman of the Section of Gynæcology, to which he had been appointed before the reconstruction of the Committee at New Orleans The Original Committee appointed at the meeting of the American Medical Association in Washington, having become satisfied that the Association at its more recent meeting in New Orleans, had a perfect right to reconstruct the Committee and order a revision of the work done, have re called their notice for a meeting of the Old Committee at Washington in September next, and formally accepted the New Committee Organization For the benefit of the editors of several of the medical journals in this country, who have captiously denounced the National Association for doing what they claimed it had no right to do, we append the following letters from the Hon Samuel J Randall, late speaker of the House of Representatives in Washington, which were presented by Dr Garnett in the recent meeting of the Committee in this City, and by vote of the Committee placed in our hands for publication It will be seen that Mr Randall fully sustains the views we gave in this Journal for May 30th and June 6th, on the same subject

MAY, 28TH, 1885

DR S W GROSS, Philadelphia

Dear Sir —Yours of the 22d inst was duly received The questions presented are somewhat novel, and are without Congressional precedent It is therefore necessary to consider them in accordance with the general principles of parliamentary law, and so far as possible, in accordance with analogous cases

The annual meeting of the American Medical Association may be said to correspond substantially with an entire Congress, or a session thereof Under the rules of the House a motion to reconsider can only be made on the "same or succeeding day," and consequently would not be in order at a subsequent session You do not state the rule of the Association on this point, but I assume there is no rule authorizing a motion to reconsider to be made at a subsequent session of the Association of a vote of the preceding session

The report of the committee under the resolutions of 1884 (though not required to submit a report), presented the entire question to the Association at its meeting in 1885, having substantially all the effect of a reconsideration of the resolutions of 1884, or in other words, as stated by Mr Cushing, "it again brings forward that question, to be discussed and decided in the same manner it was originally, for the consideration and determination of the assembly " This statement of Mr Cushing is based on decisions of Speakers Winthrop and Boyd, and is in full accordance with the established practice of the House in that respect The resolutions adopted on the 30th of April, 1885, marked " B " taken as a whole are somewhat contradictory and inconsistent The first resolution "enlarged" the original committee of seven by the addition of 38 members, and authorized the committee thus "enlarged" to review, alter and amend the action of the *present* committee as it may deem best

As the resolutions of 1884 fully authorized the original committee of seven to add to its membership and perfect its organization, it can not be claimed that in that respect it "had exceeded its powers " If the first resolution of April 30th, 1885, stood alone it is clear that the committee would consist of the original committee of seven as "enlarged under authority of the resolutions of 1884, and as further enlarged by the resolutions of 1885 But the second resolution of April 30th, 1885, expressly and in specific terms recognizes the committee as consisting of the original committee of seven, enlarged by the addition of 38 members under the resolutions of April 30, 1885, and the authority granted to select its officers and to "appoint the officers of the Congress" plainly shows that the resolutions of 1885 were intended as a complete substitute for those of 1884.

It is well settled—indeed a fundamental principle of parliamentary law—that every legislative or other body has the right to control its business by way of "instructions to committees "

It may instruct a committee to do a particular thing on Monday, amend such instructions on Tuesday, repeal them all on Wednesday, and if it pleases, abolish the committee on Thursday

In treating this subject Mr Cushing, after stating generally the powers with which a select committee is clothed for the performance of its duties, says "It is also competent for the house, *afterwards*, to enlarge the authority of the committee, either as to subject matter or its incidental power, by means of what are called instructions"

The resolutions of April 3, 1885, are therefore, in a parliamentary sense, "instructions" to the committee of seven appointed under the resolutions of 1884 In my opinion, following the rules of construction as laid down by the writers on the construction of statutory and constitutional law, which is to give effect to what was manifestly the intention of the body, and giving such construction, if possible, as will avoid contradiction and inconsistency, the resolutions of April 30, 1885, abrogated the resolutions of 1884, so far as related to the powers and duties of the Committee of Seven, and the members of the General Committee, added to the original committee, under the resolutions of 1884, were "legislated out of existence" by the resolutions of 1885 I am, yours respectfully,

S J Randall

Washington, D C

Dr A Y P Garnett, Washington, D C

Dear Sir —Yours of the 5th inst is received In reply I have to say that the questions submitted by you are substantially those presented in a letter from Dr S W Gross, of Philadelphia, of the 25th ult, and I enclose herewith a copy of my reply thereto as covering the entire ground of controversy

I might add, in addition, that the theory that a select committee created by a body with certain defined powers and duties gives any *vested rights*—so to speak—which places it above or beyond the power of the creating body to review or regulate, is one not only without precedent in parliamentary law, practice, or history, but is untenable on any ground of parliamentary principle A legislative or other body may, if it sees proper, temporarily delegate as a matter of convenience, certain of its powers and functions to a select or standing committee, but it does not thereby part with its inherent right to resume that power whenever it chooses, and that right is one which the committee can not question I am, very respectfully,

June 9, 1885 Sam J Randall

THE CONDITIONS OF CURABILITY OF PHTHISIS

Those who have read Professor Jaccoud's work on the "Curability and Treatment of Pulmonary Phthisis," are aware that he asserts that the disease is curable in all its stages, and that the dictum of incurability is but a historical souvenir It is not asserted that all cases of phthisis can be cured, however, there are certain conditions obtaining in every case, which must to greater or less extent, determine the prognosis and curability And, according to Jaccoud, the first condition of success, is the conviction on the part of the physician that the disease is curable, for it is this conviction that leads to the adoption of every possible therapeutic measure in a given case

What then, as regards the patient, are the conditions of curability? It goes without saying that "in the first place, whatever form of the complaint, whichever patient be considered, the chance of recovery is inversely as the duration and extent of the lesions," a proposition so self evident, that it need not be discussed Beyond this, there are certain indications furnished by the etiology of the disease Jaccoud has distinguished phthisis, as regards its origin, as the hereditary, the innate, and the acquired forms, the innate being that form seen in the "descendants of those who, though, not tubercular, are weakened by scrofula, cachectic diabetes, alcoholism, or simply by bad hygienic conditions," or it may be due to consanguineous marriages From the standpoint of curability, this form is more favorable than the hereditary form, which, from the fact that it is hereditary, offers the least prospect of cure for two reasons "In the first place the diathesis, that is to say, the unfortunate disposition of the organism to form tubercle, has in these cases its greatest powers," and the second place, "chronic phthisis, when hereditary, almost invariably takes the ordinary anatomical, that is the miliary form of the disease" Jaccoud distinguishes two groups of acquired phthisis First, "those cases in which the pulmonary tuberculosis, being spontaneous and independent of other diseases, could only be due to general debility, to that insufficient or improper nutrition which is the basis of all forms of phthisis, such is 'the primary form of acquired' phthisis Secondly, those cases in which the pulmonary disease is connected with a constitutional affection either past or present, and to the existence of which it may be rationally imputed, this is 'the secondary form of acquired phthisis"

As the primarily acquired or idiopathic phthisis is only produced by constitutional malnutrition, it is, as regards curability, the most favorable of all varieties of phthisis, it being supposed that the same extent of lung is involved, and it is much more amenable to treatment when it is acquired after the age of thirty five The secondary form of acquired phthisis, while much less formidable than the hereditary or innate forms, is less favorable for treatment than the primary form of the disease, phthisis, being the result, as already said, of present or past constitutional disease, and all the forms of the secondary variety, that, which is known to the authors as scrofulous phthisis is most frequent and most resistant to treatment Furthermore, it is most amenable to treatment when the lesions are confined to the lungs Of diabetic phthisis, it need only be said that it occurs late in the course of diabetes mellitus, thus adding a most serious complication to an apparently incurable disease The arthritic and herpetic forms of phthisis, not being generally recognized as true forms of phthisis, need not be discussed, and acute miliary tuberculosis, which does not produce the clinical symptoms of phthisis, may be for the present disregarded

There remain, therefore, two varieties, the so called pneumonic form, and chronic miliary tuberculosis or the ordinary form of consumption The pneumonic form of phthisis may be said to be especially curable, "it is most often an acquired or primary disease, or perhaps is connected with scrofula, receiving then the virtual advantage specially conferred by this etiological cause, the lesions are either confined to the lungs," or affect other organs at a late period of the disease Of this form of the disease, the primary period may be said to be attended by the most constant danger, as the first outbreak may prove very speedily fatal, constituting the so called galloping consumption, which is not less serious than the acute form of miliary tuberculosis The prognosis of pneumonic phthisis, therefore, depends very much upon the stage of the disease, being very serious at first, but in the period following the acute outbreak the least serious of all varieties Chronic miliary tuberculosis may be said to be the expression of a very high form of the phthisical diathesis, "the hereditary and innate diseases are usually expressed in it, and this would be the cause of its greater resistance to the healing process the lesions are almost invariably bilateral, either from the first, or before the disease has been long in existence the lesions are more disposed to increase by successive miliary as usually occurs in the disease the lesions are but rarely confined the lungs, sooner or later similar changes occur in the larynx, the intestine, and at times also in the brain," which will readily explain the unfavorable prognosis of this form But should, as may be the case, such unfavorable circumstances not exist, should this form be connected with the acquired form of the disease, and the lesions of this form be confined to to the lungs, and of small size, the prognosis may be regarded as somewhat better than that of the pneumonic form, since the primary lesions will develop more gradually "The chance of recovery, in fact, is then entirely dependent upon the constitution of the patient, which overrules at all times the question of prognosis"

The conditions of curability as regards the symptomatic phenomena remain to be considered Of these it must be said, that severe forms of laryngitis and gastro intestinal disturbances affect the prognosis to an extremely serious extent, diarrhœa due to intestinal ulceration, and ulcerative laryngitis almost necessarily indicate a prognosis of absolute incurability, as they are not only serious in themselves, but prevent the employment of most useful therapeutic agents Hæmoptysis, unless very profuse or attended by persistent pyrexia, has not the grave signification usually attached to it In some cases, indeed, it is to be regarded as a healthful process, as, for example, when in the initial period there is danger of congestion, causing an increase in the size of the lesions, "the hæmoptysis may be, as it were, critical in character, and dissipate, for a time at least, threatening inflammation" Under other circumstances, much will depend upon its frequency and effects on pre existing lesions, and "the relation which the number and abundance of the hæmorrhages bear to the condition of the organism in which they occur,"—individual peculiarities being factors of great moment

When the hæmoptysis is attended by pyrexia which persists when the former has ceased, the chances of ultimate recovery are seriously compromised Fever, of whatever type, must always be regarded as a serious matter in a phthisical case, since no improvement can take place while it lasts, and when it is complicated by hæmoptysis the condition must be regarded as unfavorable Another very important question as regards recovery is the degree and persistence of emaciation, especially when it occurs early in the disease, when it does occur early, persists and possibly increases, while the disease, as shown by the local lesions, remains stationary the possibility of cure must be excluded There is still another symptom, depending upon the character of the individual, "which should be taken into serious consideration namely the nervo vascular excitability, to which the name erethism has been applied This condition may produce mere cardiac excitability and frequent attacks of palpitation in other cases there is general nervous excitability without any pronounced visceral disturbance the prospect of recovery is diminished by its presence Symptoms such as pyrexia and hæmoptysis may be produced or continued by its existence, by producing waste it adds to the constitutional loss which characterizes the disease, and it may prevent the adoption of certain therapeutic means as residence at a high altitude, or the use of hydrocarbons as internal remedies" Besides being a serious complication, it is extremely difficult to remove, and when it is present, attempts at its removal or modification should be the first care of the physician

Such, then, are the causes, lesions and symptoms which favorably or unfavorably affect the question of curability There are, however, three other vital principles to be considered in every case the general condition of the patient, embracing the degree of malnutrition, the possibility of nutrition and what is generally known as the *constitution,* secondly, the existence of or freedom from intercurrent attacks of congestion or inflammation, and thirdly, the possibility of proper treatment, which involves the consideration of the means for treatment at the patient's disposal "Nothing is so complex, so difficult to conciliate with the ordinary habits of life, so costly in expense, as the treatment of pulmonary phthisis The disease may remain incurable, not on account of its own serious nature, but because it cannot be completely or constantly resisted and the disease is therefore quite different as it affects the rich or poor, so far as the result of treatment is concerned"

SOCIETY PROCEEDINGS.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE.

Stated Meeting March 11, 1885.

THE PRESIDENT, DR. R. T. EDES,
IN THE CHAIR.

DR. V. Y. BOWDITCH reported a case of

TRAUMATIC LINEAR ATROPHY.

During the past year my attention was called to an affection of the skin, the symptoms of which were so marked and peculiar, that I have thought it worth while to present the case to you this evening.

Mrs. A., a widow, aged sixty, with children, a person of decidedly sensitive and nervous temperament, has had for many years slight aortic disease, which in the last two years has shown somewhat more marked symptoms, together with a decided increase in bodily weight. Early in the past year, she began to have an annoying paroxysmal cough, which, after repeated examinations of throat and lungs, with negative results, I came to the conclusion, was of nervous origin, and, owing to her generally debilitated condition I prescribed change of scene and air, and sent her to a relative's house in the country. On the twenty-sixth of February, a year ago, I was called to see her, and found the cough was still quite severe, at times causing vomiting and much dyspnœa. The patient complained also, of an extreme sensitiveness confined to the lower abdomen. Upon examination, nothing abnormal was to be seen, but upon palpation, the walls of the abdomen, which was large and pendulous, were very sensitive, which symptom I regarded as rather hysterical than otherwise. I prescribed, however, a liniment containing aconite root and chloroform, with soap and opium and did not see her until the following week, when she sent me word that several small puffy excrescences had appeared upon the abdomen, accompanied by a feeling of great heat and distension. Upon examination, the lower quarter of the abdomen down to the pubes and Poupart's ligament was very hyperæmic, and, ramifying in every direction upward, were curious, whitish, œdematous looking elevations from one eighth to one-fourth of an inch in width, most marked near the pubes and median line, and gradually disappearing toward the line where the hyperæmia ceased, the whole having in arrangement the appearance of the branches of a tree, and giving to the finger, the sensation of very soft, crumpled rice paper. I ordered the liniment to be discontinued, and a lotion containing the acetate of lead was substituted. The following week, the hyperæmia increased, and the elevations had increased in size, in some places having coalesced so much as to make lumps as large as half of a pullet's egg. There was no marked tenderness, but a feeling of heat and puckering all the time, with a sense of distention of the parts, which caused much discomfort to the patient when sitting upright in a chair. The general symptoms were not materially changed.

Not being satisfied with the course of the trouble I called in consultation Dr. J. C. White, who considered it a very marked and rare case of either linear atrophy or keloid, and recommended leaving off all applications and using an abdominal supporter to relieve the tension of the skin. Owing to delay in obtaining the supporter it could not be applied until some two weeks later, and as the hyperæmia and the elevations seemed to be slowly disappearing, I decided not to use the supporter, and see if the abdomen would not regain its natural appearance without aid of any sort. Two weeks later, the hyperæmia and swelling had entirely disappeared, leaving only numerous cicatrices similar to those noticed on the thighs and abdomen of a woman who has born children, or whose abdomen is large and pendulous.

In the *Journal of Cutaneous Medicine* (vol. i. p. 140) Sir Erasmus Wilson speaks of "Striæ et Maculæ Atrophicæ Cutis, or false cicatrices of the skin." By these names he designates the whitish, slightly curved, puckered streaks so well known to us as seen on the abdominal walls and thighs of women who have born children. He considers that these marks are due to rupture of the corium, with loss of the subcutaneous fat, of the papillary layer of the derma, of its vessels and nerves, leaving a smooth and unmoulded epidermis. From this loss of substance arises the name of striæ atrophicæ, or linear atrophy. He mentions, also, the existence of similar false cicatrices in the skin which have arisen under different conditions from those of pregnancy, and divides them, according to the nature of their origin, into three classes of linear atrophy, namely: (1) neurotic, (2) traumatic, and (3) idiopathic.

Under the first head come the lines sometimes noticed over the course of cutaneous nerves which have been paralyzed. For instance, in cases of paralysis of the supra orbital, the course of the nerve can be traced by the whitish line which marks the position of the nerve, and which, some time later, loses its sensibility and becomes atrophied, resembling the scar of a sword cut, the line in this case being more firm and condensed than in the other forms.

Under the second head, namely, the traumatic form, Wilson considers all those cases which arise from overdistension of the skin from causes acting from within, and mentions the conditions of pregnancy, of dropsy, and obesity. He likens this condition to that of a rubber bag which is overdistended with gas, it first yields, and then gives way at the weaker places. He concludes: "In the corium, this violence is accompanied with hyperæmia and followed by exhausted nutritive power and atrophy."

The third, or idiopathic, form he considers appears without apparent cause, although the nutrition of the skin is evidently affected by an unhealthy general condition. Unlike the traumatic form, moreover, it appears in parts of the body not subjected to distention of any sort.

This case I class under the second head, namely, linear atrophy of traumatic origin. We have the history of long-continued paroxysmal cough, causing frequent and violent distention of the abdominal walls, which, owing to the debilitated condition of the patient, yield in the manner mentioned above, and after two or three weeks of acute hyperæmia and swelling, a gradual diminution of the symptoms occurs, until no vestige of the trouble is left except the small cicatrices of the ruptured corium.

In this case the symptoms were all unusually well marked, and to one whose attention had never been called before to the affection the appearance was decidedly puzzling, not to say alarming.

Diagnosis.—The only other disease with which linear atrophy could be confounded is the so called "keloid," and several authorities speak of the marked similarity between the two affections, and the frequent difficulty of distinguishing one from the other. Cases of the latter are divided by most authors into two classes, namely, the true and the false keloid, according to the idiopathic or traumatic origin of the affection.

True keloid is the name applied to an affection characterized by a collection of small red tubercles, usually found upon the sternum, sides of the body and back, which increase in size slowly until they coalesce, forming oval or cylindrical-shaped tumors, dry and puckered in appearance, with spur like processes, somewhat tender upon pressure, and firmly rooted in the skin. This process of growth may go on for months or years with more or less discomfort to the patient from a sense of burning or itching, and the affection rarely disappears, although exceptional cases are reported in which entire disappearance of the tumors was noticed. False keloid is a term used to designate the exaggerated cicatricial tissue noticed in places where a wound has previously existed, and differs from the true form in that it is usually smaller, longer, bifurcating and follows the course of the original lesion. The difficulty oftentimes of drawing the line between true and false keloid is spoken by Kaposi in his article on "Keloid," Lehrbuch der Kinderkrankheiten, vol. ii.

The course of the disease, its sudden appearance and comparatively rapid disappearance, the absence of tenderness in the tumors themselves, are facts which enable us to decide against the presence of keloid in the present case. The slight elevations noticed, resembled the tumors of that disease, but their rapid shrinking, leaving nothing but the ordinary atrophic lines, is another proof of the non existence of keloid.

Treatment is of little avail in these cases, and the disease will, as a general rule, run its course uninfluenced by medication. Attention to the general health and an attempt to remove the exciting causes are chiefly indicated, as in this case, for instance, where an attempt was made to relieve pressure on walls of the abdomen by means of a supporter, medicines to relieve the paroxysmal cough were given. Sedative applications are of little or no use in checking the course of the affection.

In conclusion, the question might naturally arise—Could the affection described have arisen from the application of the liniment containing aconite-root and chloroform, with soap and opium? Such a supposition can hardly be sustained: *first*, from the fact that no case has ever been recorded of similar trouble arising from the use of this very common remedy; *second*, because attention had been called to the extreme sensitiveness of the lower part of the abdomen before any external applications were made; and *third*, because similar affections, in which the general symptoms were like those mentioned in this case, have been recorded by various authorities.

DR. WHITE, in discussing the paper, stated that the process is not a true atrophy, but an over-stretching of the skin by which its elastic fibres lose their contractility, and the bundles of fibrous tissue forming the skeleton of the corium and normally interwoven in the form of a network, are pulled out straight and left in a permanently parallel direction. The papillæ and the glandular structures are pulled farther apart, and the former flattened down. The stretching of the corium might result in real fracture of its tissues. The process is at times accompanied by hyperæmia, so that the streaks looked redder than the surrounding skin seen through the stretched and thinned epidermal layers. The cause is always a distension of the integument by some power acting beneath it, as pregnancy, a rapid accumulation of subcutaneaus fat, ascites, and the like, and occurs principally over the abdomen, breasts, and thighs. It affects men as well as women, and may possibly be caused by rapid increase in size in young people. The present case presented some very uncommon features. The hyperæmia and tenderness or the parts were as pronouncod as in an active dermatitis. The elevation and firmness of the radiating ridges resembled keloid or hypertrophied scar formation, and must have been due to the presence of the products of inflammatory infiltration. The exciting cause was apparently the rapid accumulation of subcutaneous fat and the rending action of the spasmodic cough.

DR. EDIS asked the distinction between the scars of linear atrophy and those of pregnancy, and how the distinction can be recognized.

DR. WHITE stated that at times hyperæmia may accompany œdema.

DR. H. I. BOWDITCH asked if the liniment applied could have caused or increased the hyperæmia?, to which the reader replied that in his opinion this could have had nothing to do with it.

DR. LYMAN observed that we see similar cicatrices on the thighs of virgins and others who have never borne children.

DR. WHITE admitted that this may occur, but it is generally in persons who have a large amount of fat, and results from simple distension. It is at times seen in the breasts of fleshy women. It is not a true atrophy, but results from a mechanical pulling out of the tissues from simple distension.

DR. F. C. SHATTUCK read a paper on

A CASE OF MULTIPLE SARCOMA OF THE SKIN — TREATMENT BY SUBCUTANEOUS INJECTIONS OF FOWLER'S SOLUTION, WITH RECOVERY.

July 26, 1883, K. B., 31 years old, was admitted into the Massachusetts General Hospital. Her health had usually been good, and she had worked at dressmaking up to the time of admission. Seven months before that date she began to suffer from pain along the lower jaw, and soon after noticed swelling behind the angles of that bone. About two months later, nodules appeared in the skin over her right shoulder, then on her right arm, next on the left, next on the abdominal wall. She thinks that the appearance of the nodules was preceded by local tenderness and followed by discoloration. About three weeks ago she noticed that her face was fuller than normal, and she began to suffer from pain in the cardiac region. She was somewhat short of breath on exertion, and reported that she had lost decidedly in strength, though not in flesh. The bodily functions were in fairly good order. Pulse 120, regular, rather weak.

On examination, it was noted that the patient was pale, with some œdema of the eyelids and face, preponderating on the right side. Scattered throughout the skin of the upper extremities and the body as far as the umbilicus were hundreds of nodules, mostly about the size of a pea. Over the inner aspect of the arms the nodules were discrete, not raised above the surface, slightly tender on pressure; the skin could be wrinkled over them, and was not discolored. On the other hand, over the shoulders, outer aspects of the arms, breasts, upper abdomen, and back—though in the latter situation to a less degree—the nodules were so thickly sown as to form large masses or plates, very hard and but very slightly tender; the skin covering these could not be pinched up or wrinkled, and was markedly erythematous, with slight scaly desquamation of the epidermis. In the legs a very few nodules could be felt, and there was no erythema. The glands at the angle of the jaw were enlarged, but those of the axilla and groin were apparently normal. Thorough examination failed to reveal any material modification of the great viscera. I made the diagnosis of multiple sarcoma of the skin, and soon after Drs. White, Wigglesworth, and Tilden were kind enough to accede to my request to see the patient, concurring in the diagnosis.

General tonic treatment was prescribed at first, but Kobner's brilliant success in a similar case with the subcutaneous use of Fowler's solution induced me to adopt his plan toward the end of August. An injection of four minims, diluted with an equal quantity of water, was given once daily, deep in the thigh. September 15 Dr. Tarbell resumed charge of the wards, and soon after increased the injection to six minims. The general health of the patient improved, a few fresh nodules appeared, but the old ones disappeared in much larger numbers, and November 3 she was discharged from the hospital, in order that she might work a portion of her time. She came daily to the hospital, however, for her injection, until she was furnished with a syringe and taught its use, and treatment was persisted in steadily till the middle of March, when I opened an abscess in the thigh, the only one which formed during the whole time. A few nodules still remained, but the masses which filled the skin over the breasts, abdomen, and outer side of the upper arm had entirely disappeared, and during the past year she has been under observation from time to time without any treatment whatever, and has worked steadily at her trade. I have seen her within a few days, and she remains perfectly well to all appearance.

Early in 1884, I showed her at a meeting of the Medical Improvement Society, but have purposely allowed a year to elapse before reporting the case, in order that there might be no doubt as to the result.

Cases of multiple sarcoma of the skin are rare, and the authorities on diseases of the skin have little to say on the subject. All agree that the prognosis is absolutely unfavorable, and the course generally a rapid one. Kobner's is the only case recorded up to date, so far as I am aware, in which recovery took place. I now regret that one of the tumors was not excised and examined microscopically, as was done by Kobner. The patient was extremely averse to the operation, and preferred to wait, promising that she would make no objection if she got worse. To this delay I consented, having very little faith that treatment would prove of any avail. Still, even without the evidence without the evidence of the microscope, I think there can be no doubt as to the diagnosis. The experts were unanimous and I had previously seen two other cases very similar, except that they ended fatally. Was the cure really attributable to arsenic? If so, would the drug have acted as well administered in the usual way by the stomach? These are questions which can only be answered by extended experience. It is interesting to state that ten days after the arsenic was stopped the urine was examined for its presence by Professor Wood, with a negative result.

Dr. White stated that two years had passed since the last report on Professor Koebner's case, and so far as he knew, the patient remained well. He saw no reason why the internal administration of arsenic should not work as effectually as the subcutaneous injection. He had at present a similar case of multiple sarcoma under treatment by Fowler's solution given by the mouth, but it was too early as yet to report results. Some forms of sarcomatous growths in the cutaneous tissues showed a marked tendency to spontaneous involution, that is, if we regard the so-called mycosis fungoides, or granuloma fungoides, or lymphadenoma, etc., as it is variously titled, of this nature. In this affection, of which he had had recently two examples under observation, tumors the size of a hen's egg or larger will rapidly disappear notwithstanding its malignant character. The pathology of this form of disease was not yet fully established, and, although several excellent microscopists had determined the presence of a sarcomatous structure in it, clinically it was distinct from the form presented in Dr. Shattuck's case. Pigmented sarcoma did not appear to undergo involution with or without treatment. In reply to Dr. Blodgett's comments he stated that he saw no reason why a sarcoma should not confine itself to the cutaneous tissues in some cases, just as carcinoma may be restricted for an indefinite number of years to the same structures without manifesting a tendency to invasion of other parts of the system or to general malignancy.

Dr. Tilden showed the photographs of a case interesting in connection with Dr. Shattuck's paper. The case had been under Dr. Tilden's observation, having been sent to him by Dr Vincent Bowditch and had been referred to by Dr White as a variety of cutaneous sarcoma The disease was more common than that which Dr Shattuck had reported, there being recorded in medical literature from thirty five to forty cases In the majority of cases it occurred in the male sex, and most commonly in advanced middle life from forty to sixty years The malady had no connection with syphilis, and most of its victims had always been in good health It began with fugitive erythematous, and inflammatory lesions of the skin, attended with great itching and desquamation After this condition of the skin had lasted some time, a year or more, there appeared the lesions which were characteristic of the disease, namely, cutaneous tumors appearing either on normal skin or in regions which were already affected by the inflammatory lesions already mentioned These tumors increased in size until often the epidermis covering them was cast off, exposing to view the pathological tissue of which they were composed, from which exuded a thin fluid which dried and formed crusts The most remarkable feature of these tumors, and one which had been mentioned by Dr White, was that they often spontaneously and completely disappeared, apparently by reabsorption, at the same time that other lesions of a like nature were showing themselves in other parts of the body The disease is of chronic course and fatal termination, and its clinical features are well understood, Bazin's excellent description leaving nothing to be desired in this connection Its pathogenesis, however, has yet to be determined It is regarded by Kaposi and also in this country as multiple sarcoma of the skin, while several German authorities look upon it as a granulative tumor of the skin, giving to the disease the name of granuloma fungoides The French dermatologists regard the affection as belonging to the same category as Hodgkin's disease, or pseudo leukæmia, where, without marked or permanent increase in number of the white corpuscles of the blood, there occurs general hyperplastic enlargement of the lymphatic glands and spleen, together with the formation of so called cytogenic or lymphatic tissues in various parts of the body Microscopic examination showed the tumors to be made up of a dense infiltration of the corium with round cells resembling lymph cells which, according to Ranvier, were contained in a fine, fibrillary network, presenting stellate connective tissue cells at the points of intersection of the fibrillæ, the presence of this network showing the new formation to be one of cytogenic tissue, and not sarcomatous in nature Dr Tilden had excised two of the tumors from the question, but had not yet had time to give them a thorough examination, and was of the opinion that if the presence of this lymphatic reticulum could be satisfactorily made out, that it would go far toward showing the cytogenic nature of these tumors In determining the pathogenesis of any malady also, its clinical course should be taken into consideration as well as the minute anatomy of its pathological products, and the malady in question had many of the clinical features of pseudo leukæmia In none of these cases had there been observed sufficient increase in number of the white corpuscles of the blood to constitute typical leucocythemia, and at the autopsies, as a rule, there had been found enlargement of the lymphatic glands, and often also of the spleen The last case which had been reported was by Auspitz, in Vienna, last December, and in this case the tumors, upon investigation, have been found to contain large quantities of micrococci Considering, however, the extremely favorable conditions in the shape of warmth and moisture furnished by these fungous excrescences deprived of epidermis, any microorganism found in them can hardly be regarded as anything but an accidental phenomena

Dr **Lyman** stated that he had a case under observation in which the features were similar to those described by Dr Shattuck The patient was seen some twelve or thirteen years ago The skin was covered with small tumors The patient died, and on autopsy similar growths were found in all the internal organs Dr Lyman asked if arsenic is usually given in doses so small as those reported

Dr **White** replied that the amount given is never more than three minims at each injection

Dr **Shattuck** stated that the amount of the injection in the present case was increased to nine minims There is an objection to large or bulky injections in that they sometimes produce severe pain at the seat of the injection

Dr **Blodgett** considered it a matter of regret that a portion of one of the suspected growths was not removed and subjected to microscopical examination The clinical history of the sarcomata is generally that of a most malignant form of disease, which tends to advance locally, and is often followed by degenerative changes in the growth, by which loss of substance and an ulcerating substance is produced One of the most uncontrollable and persistent features of sarcomatous disease is also found in the tendency which these growths possess of forming metastatic deposits in remote portions of the body, and especially in the structure of the visceral organs Each local deposit forming a new and independent local development of the original disease

The specific treatment of sarcoma would seem to offer, *a priori*, less promise of success than would that of sarcinoma, as the latter is confined originally to epithelial structures and is essentially an affection of an external surface of the body, while sarcoma is developed in the connective tissue, the *universal* tissue of the interior of the animal body

Dr **Blodgett** suggested the possibility of the existence of a disease in the connective tissue which might resemble sarcoma in appearance as the innocent verruca or common wart resembles a form of malignant carcinoma called papilloma so closely that by the microscopical examination alone one might not be able to say which was malignant

For this additional reason it would be of great advantage to secure a careful microscopical examination of the tissues in cases of this kind

Dr **White** added that there is at present no known method of treatment which offers any promise of relief or cure in sarcoma In ordinary cases the disease progresses in a way which shows the powerlessness of all medicinal measures for its restraint or cure. He suggested that in the absence of microscopical examination of the tissues it is possible that some other condition than sarcoma may exist.

The Secretary called the attention of the Society to a card which had been sent him, announcing the presence in the city of a so called "hermaphrodite," and stated that in company with three prominent members of the profession from Park Square he had visited the individual for the purpose of offering at the meeting of the Section a favorable opportunity for introduction to the profession as the most useful method of attracting the notice of persons interested in such a malformation.

The efforts of the Committee were not crowned with success owing to the high pecuniary consideration which was demanded before even an ocular view of the deformed region could be obtained.

The contradictory statements made by the individual led the Committee to doubt the existence of hermaphroditism, and they consider it probably an abnormal or unfinished condition of male development.

Dr. James J. Putnam described briefly a case of typical hemianæsthesia, involving all the special senses, which had developed in a strong, healthy man as the result of a concussion two years before.

Conclusive evidence against malingering was furnished by the fact that the lines bounding the anæsthetic region of the skin and the diminished field of vision were preserved throughout a protracted examination. No outward sign of disease existed and the medico-legal value of the symptoms described was obviously great.

Dr. Edes remarked that he had a male patient at the hospital last year who, after a fall with loss of consciousness and tempory hemiplegia had hemianæsthesia of the most distinct character.

The field of vision was very much diminished on the affected side, and also the color fields almost as exactly as if the man had studied and remembered Charcot's description of similar cases. Smell, taste, and hearing were diminished on the same side.

INFANTILE DIABETES.

Dr. White stated that he had recently seen a female child, aged two years and three months, the inner surface of whose vulva as well as the perineum as far back as the anus, was intensely inflamed, being uniformly excoriated and in parts in a condition of superficial ulceration. Being reminded of similar forms of dermatitis of these parts in adult life, he made inquiry which showed that micturition was too frequent and that the diapers stiffened on drying. Analysis of the urine subsequently made revealed a large percentage of sugar, specific gravity 1042.

The inflamed parts were rapidly improving under black wash and a protecting ointment.

KENTUCKY STATE MEDICAL SOCIETY.

Thirtieth Annual Meeting, held in Hustenville, June 24, 25 and 26, 1885.

WEDNESDAY, JUNE 24, FIRST DAY.

The Society was called to order by the President Dr. Pinckney Thompson, of Henderson. Rev. J. R. Roger, of Hustenville, O., opened the session with prayer.

Col. Will S. Hayes, of the *Louisville Courier-Journal*, made a happy Address of Welcome.

Dr. Edward Alcorn, of Hustenville, chairman of the Committee of Arrangements, also spoke some words of welcome.

Dr. Will Bailey, of Louisville, from the Committee on the

PRACTICE OF MEDICINE

spoke of the common practice on the part of the pharmacists of loading down the physicians office table with new pharmaceutical preparations. He thought this had become a common nuisance and should be abated. He had not the courage to uncork one tithe of what he received. He thought the physician should go before and ask the pharmacist to make new preparations to meet his wants, not that the pharmacist should form the remedies, and then urge them and their merits upon the physician. He recommended that new remedies be thoroughly tried by competent men in public institutions, then if found worthy, given to the general profession. He then began the discussion of the subject of cholera. All honor should be given to the brave men who are risking life and sacrificing comfort in the etiology of the disease. He thought the germ theory of disease to be the greatest question of the age. He thinks that from the history of cholera it must be much like dysentery, malarial fever, etc., due to climatic influences. In cholera improved sanitation should be the watchword.

Dr. Pinckney Thompson, of Henderson, then delivered the

PRESIDENT'S ADDRESS.

He congratulated the Society on their ability to meet together, and referred to those who had joined the great majority. He spoke of the profit to be gathered from their meetings, of all taking part in the work. A wise old Roman long since said "Men are at no time so like the gods as when they try to give health to other men." He who assumes the office of a physician takes up a solemn trust, a very grave responsibility; neglect or abuse must be most culpable. The physician he said was responsible for many of the crimes of the world, for to whom are the feeble constitutions and defective intellects more chargeable. To have a good brain we must have good blood. Whence can good blood, physiologically, come to him who has been born and bred in disregard to the laws of health? Wanting good blood the brain power fails, then the whole life, mental moral and physical fails, and degradation results. He then considered the physical, mental and nervous degeneration of the American women, and "Over-pressure at School." He compared the children of the cities with those of the country. Who of us have not seen, again and again, their country boys come to the town or city, and with their robust constitutions and heads full of brains, ride over their city or town competitors in whatever occupation they may follow? The women of this generation, he thought, had not improved intellectually, physically, or otherwise over the preceding one He should like to say that every girl is an angel and every woman a goddess, but if so they are very sick angels, and very feeble goddesses He laid special stress in the difference of school life in the city and country, and its effect on the health of the children The city schools he termed elevated slaughter houses He spoke of the fearful increase of "Gynecological Sanatana" He closed with an appeal to the profession to correct these evils as far as possible, and to educate the people, especially mothers, in the proper care of their daughters

THURSDAY, JUNE 25, SECOND DAY

The Board of Censors of the Boyle County Medical Society reported the names of two gentlemen as not being members of the County Society As no charges were made against the gentlemen other than this the matter was referred back to the local Society

The Secretary, S M LETCHER, M D, reported that the sum of $100 had been contributed to the Sim's Memorial Fund Received from dues $200, leaving $75 05 in the treasury

A communication was received from the American Medical Association recommending that the State Society use its efforts to secure the passage of a bill authorizing the forming of a

STATE BOARD OF EXAMINERS AND LICENSERS

Referred to a committee to report

The subject of the

IMMIGRATION OF INSANE AND DEFECTIVE PAUPERS

into the United States from European and Asiatic countries was referred to a committee to report

DR J M MATTHEWS, of Louisville, read the report on the

PRACTICE OF MEDICINE

He commenced with a feeling reference to the death of Dr Gross He then considered the operation of abdominal section and hydrochlorate of cocaine He thought it an important question as to whether cocaine prevents repair In some of his cases he thought it had Its use in rectal diseases had not been followed by success in his hands He had also used rhigolene as a local anæsthetic with success He thought the great question to be, Can a physician after attending autopsies or infectious diseases disinfect himself and go to the operating room or lying-in chamber? Abdominal section for gun-shot wounds, pylorectomy and surgical treatment for empyema were carefully discussed

DR WM CHEATHAM, of Louisville, thought the essayist was mistaken in his reference to cocaine preventing repair Secondary hæmorrhage is more likely to occur He thought it had a styptic action

DR M F COOMES, of Louisville, thought that if he had a gun-shot injury of the abdomen and the surgeon exhibited any hesitancy about operating he would say "go ahead" If cleanliness is observed in the abdomen repair will occur as quickly here as elsewhere He reported a case of toxic symptoms following insufflation of two grains of Iodoform

DR E WILLIAMS, of Cincinnati, discussed the subject of cocaine He had arrived at the conclusion that the preparation of Merck was much superior to that of any American manufacturer He had removed a small cystic tumor above the eye, using hypodermic injections of cocaine Pain was not entirely abolished

DR AP MORGAN VANCE, of Louisville, said that his experience was different from that of Dr Williams He had found it to work admirably in all cases even of tumors He reported a number of cases,

DR W O ROBERTS, of Louisville, had used cocaine His experience was not uniform, sometimes it does well but it sometimes fails In operations on the rectum it is of no use at all He had used it in stricture of the urethra, and in prostatic and vesicle trouble, with good results

DR ARCHIBALD DIXON, of Henderson, reported on

LAPAROTOMY

He reported a case of abdominal tumor believed to be fibroid producing ascites In four months after it came under his observation the tumor increased considerably It continued to grow despite ergotine injections until it occupied the entire abdominal cavity The operation for removal was successful

DR T B SCOTT, of Louisville, asked, How much may a physician expose himself to post-mortem examinations and infective cases and then attend obstetric cases?

DR T A REAMY, of Cincinnati, at the request of the President, replied to this question He referred in favorable terms to a paper read by Dr Geo F French, of Minneapolis (see p 5 of this issue of the JOURNAL), before the obstetrical section of the American Medical Association, "How Soon After Exposure to Sepsis may a Physician Resume Practice!" He would have it known that the germ of the dissecting room had been shown to be a different thing from that of disease He stated how he had attended a case of puerperal fever in the morning, took a bath in warm water, then one in carbolized water as strong as he could bear it, then dressed himself He said if an obstetrician was called on to attend a case, it was his duty, in attempting to disinfect himself, to change all his clothing clear down to his socks, take a shampoo, then bathe well in warm water, and then take a disinfecting bath No man had a right to attend a case after attending an infected case unless he did that While he might go in consultation, he was not fit to take charge of the case

The Committee on nominations referred the following names

OFFICERS FOR THE ENSUING YEAR

President, J P Thomas, M D, of Pembroke, Sr Vice-President, O D Sharley, M D, of Winchester, Jr Vice President, R C McChum, M D, of Lebanon, Permanent Secretary, J Steel Bailey, M D, of Stamford, Treasurer, Edward Alcorn, M D, of Stamford, Librarian, J L Taylor, M D, of Warren Co, Chairman of Committee of Arrangements, S W Willis, M D, of Winchester Winchester was chosen as the next place of meeting, time, the last Wednesday in June, 1886

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT)

Diet of Nurses in Hospitals and Infirmaries—A Hæmostatic Powder—Professor Budin—Causes and Prevention of Cholera—The British Gynæcological Society

At the sixth general meeting this season of the Hospital's Association, held at the rooms of the Social Science Association, a paper was read by Miss Louisa Twining, entitled "Thoughts on the Diet of Nurses in Hospitals and Infirmaries" She commenced, by stating her conviction, that the health of nurses in hospitals was not sufficiently considered in the arrangement of the dietary Motives of economy might probably be pleaded, but no motive should prevail which seriously affected either the present or future health and strength of young women The result could only be a speedy break down, or a lingering debility It would be granted by all, that the work of a nurse was not one conducive to appetite Their avocation would indispose them to a hearty relish of their food The apparently inevitable arrangement that the nurses dinner followed immediately upon that of the patient, was not the best preparation for their own meal Far greater attention should be paid to providing suitable food for nurses, and that would be in the end true economy Two things were named as capable of improvement, viz, making the dining rooms and tables a little more attractive, and also the extension of time allowed for meals, nurses so often hurrying over them, to the serious injury of their digestion, and the entire absence of any enjoyment of their food More changes in the way of soup, lentils, fish, etc, were needed The The substitution of more coffee or cocoa for frequent tea would be an improvement, and without adopting the vegetarian system, many useful hints might be obtained from it In concluding, Miss Twining alluded to the question of stimulants, which was now being considered from all points of view She objected to the allowance of money instead of beer, as the temptation was to get stimulants outside of a stronger character She advocated the necessity of an officer being present at all meals to see them properly served, and in sufficient quantity All the opinions she had obtained pointed to the same direction, viz that greater variety was needed even more than quantity, and that the quantity of meat should be reduced in favor of more vegetable and farinaceous food, that greater attention should be paid to the cooking of the food, to the serving of the meals, and all the necessary accompaniments As she was convinced that women were the best judges of such domestic matters, she ventured to call the attention of all lady guardians, especially, to these matters in infirmaries and work-houses, believing that no more important subject than this could claim their care and consideration

At a recent meeting of the Academy of Medicine in Paris, Professor Bonafoux read a paper upon a powder which posesses great hæmostatic powers, and is capable, it is said, of arresting the bleeding of large arteries, so that it will prove serviceable in important surgical operations This powder is composed of equal parts of colophony, carbon, and gum arabic Experiments have been made with it on the brachial artery in man and on the smaller vessels, on the carotid of the horse and other vessels of the same animal, with marked success It has always prevented consecutive hæmorrhage The application can be lifted in the course of two days, when the vessels are found to be completely obliterated

Professor Burdon Sanderson delivered a lecture at the Royal Institution on "Cholera, Its Causes and Prevention" Sir Frederick Abel presided The Professor gave a short history of the manner in which at various periods the disease had spread, and said that those who resided at the West and North of London need have no fear as to the cholera if it fixed itself again in the east of the Metropolis, but he ventured to predict that if the disease intended to attack London this year, it would long ago have been on the march

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT)

Rupture of the Perineum—The Forceps and Chloroform in Labor

The New York County Medical Association brought the year's work to a close in a very satisfactory manner at its last meeting before the summer vacation, which was held on the 15th, at the Carnegie Laboratory To show that it was a pretty full evening's entertainment, as well as to indicate the quality of the same, the order of exercises is herewith appended

I 8 P M A few practical remarks on Rupture of the Perineum By Frank H Hamilton, M D

II 8 30 P M Persistent Flatness over the Liver, as proof that Acute Diffuse Peritonitis is not associated with Intestinal or Gastric Perforation By Austin Flint, M D

III 8 45 P M Intussusception of the Intestines, with the report of a case By Charles S Wood, M D

IV 9 10 P M A Method of Direct Local Treatment for Diseases in the Region of the Ileo Cœcal Valve, and also for the Safe Removal of Impactions of the Intestines By Charles A Leale, M D

V 9 20 P M Presentation of Specimens

VI Discussion of Papers in their numerical order

VII Executive Session

In presenting his paper, the venerable surgeon who was first on the programme explained that he would be unable to read it himself for lack of voice, as he had been that day no less than nine hours on the witness stand (in connection with the famous Hoyt will case), and he therefore called upon the corresponding secretary, Dr John Shrady, to read it for him

Many of the views expressed by Dr Hamilton were somewhat at variance with those commonly entertained at the present day though there was very much sound common sense in the paper. It was unjust, he thought, to say that rupture of the perineum was an accident which could always, or even generally, be prevented by the skill of the accoucheur, since its occurrence was often due to conditions and circumstances over which the latter had no control. Thus, the perineum may be unusually deep in its antero-posterior diameter, or unusually thin and delicate, or less elastic in its texture than natural, the sacrum and coccyx may not have the proper curve to direct the head towards the pubes, the head itself may be large and unyielding, the uterine contractions may be too violent and rapid to allow the perineum time to become gradually stretched and accommodated to the head. There were, indeed, many causes, he said, which might determine this result, which were wholly beyond the power of the accoucheur to control.

The idea of "supporting the perineum," as commonly inculcated by obstetrical teachers, he believed could not be sustained either by any sound mechanical theory or by experience. If the intention was to delay the advance of the child, the intention was a good one, but this method of seeking to accomplish it was of no value. No resistance, or none which could ever be considered justifiable, applied to the perineum, could appreciably delay the advance of the child when the uterus was acting with its normal or with unusual vigor, and under no other circumstances would it be required. If the purpose of making pressure upon the perineum, however, was to carry the head forward toward the pubes, the suggestion had a meaning, and could be understood. This was certainly advisable whenever, from the lack of curve in the sacrum and coccyx, or from any other cause, the vertex did not take this direction, but these examples were rare and exceptional.

Sometimes, of course, the accoucheur was responsible for the accident of rupture, but his responsibility was likely to consist in what he might actually have done, rather than in what he might have omitted to do. Some modern authorities did not think the danger of rupture of the perineum was increased by the use of the forceps, if they were only used skilfully, but it certainly must increase the danger if they were used unskilfully, and when, in the hands of even the most skilful, the instrument was retained in position until the head had entirely escaped from the vulva. Nor did it appear to him that the argument in their defense was conclusive, even when the forceps were employed only to bring the head into the lower strait, and then withdrawn, leaving nature to complete the recovery. It was claimed that by this simple manœuvre the process of natural labor might often be greatly expedited, but this was the very thing which, according to his notions, it was generally most desirable to avoid, so that the perineum, as Meigs used to say, might "not be taken by surprise." In short, there was less danger to the perineum when the head did not come upon it forcibly and unexpectedly, and before the head itself had undergone the process of moulding and elongation. Dr. Hamilton, in referring to the fact that since the time when he commenced the practise of medicine the question of instrumental labor had undergone a complete revolution, said: "I was a pupil of Dewees, and was taught that the forceps was seldom required, but to-day the teaching is altogether different, and there are now many gynæcologists who count their instrumental labors by the thousands. A young man who was urging me to apply the forceps to his patient, but in which case the result proved that it was unnecessary, told me that a friend of his, a recent graduate of one of our city schools, and who was doing a large obstetrical practice in a neighboring town, assured him that he never put a woman to bed without forceps. I do not hold this young man's teachers responsible for his practice, but the fact illustrates what is now the drift of professional opinion."

As far as he was able to judge from the obstetrical experience of his early life and the surgical experience of his later life, grave perineal lesions were more common now than formerly, and this increase had been coincident with the increased use of forceps and of anæsthetics in labor. The effects of anæsthetics were by no means in all cases limited to the alleviation or abolition of pain when employed in the case of the parturient female. In most cases they exerted a positive influence upon the uterine contractions, and in this respect they were capricious, not infrequently increasing the frequency and strength of the contractions, and thus contributing to the production of a perineal rupture. In other cases he had seen the contractions temporarily suspended under their influence, and serious uterine inertia induced. "While there can be no doubt," he continued, "that the forceps and anæsthetics have been of incalculable service to parturient women, I have a strong conviction that, since they have come into such common and almost universal use, they have done a great deal of harm. I believe that the time is not distant in the future when it will become apparent to all that we have in these matters progressed too rapidly, and possibly that our progress has been altogether in the wrong direction."

In case a perineal laceration involved any considerable portion of the perineum, extending nearly or quite to the outer surface of the sphincter ani, the closure of the rent was desirable, inasmuch as in a certain proportion of cases it was followed by a relaxation and falling of the vaginal walls, with a consequent displacement of the uterus, though it had often happened to him to see women in whom the rent had extended through the entire perineum, who had after the lapse of many years suffered no inconvenience from this source. The occurrence of a deficient perineum and of prolapsus uteri did not always stand in the relation of cause and effect. The perineum in its most perfect condition, and when the uterus occupied its normal position, gave no direct support to the latter, and the uterus might be made to descend from many causes, whether the perineum were sound or not. The absence of the perineum, when the vagina and uterus were in their normal conditions, could only influence the descent of the uterus by first inducing atony of the muscular fibres of the vagina, with congestion and prolapse of the vaginal walls, by which not only the feeble and indirect support which the perineum gave to the uterus was removed, but the vaginal walls became a dead weight to drag the uterus downward

Dr Hamilton said he could not agree with some modern gynæcologists as to the advisability of the immediate or primary operation The parts have suffered such a degree of stretching and contusion as to render the occurrence of inflammatory reaction, if not of sloughing, almost inevitable, the lochial discharges will make it impossible to keep the parts clean, the operation itself inflicts a severe injury when the condition of the patient is already critical from other causes, and, finally, because under judicious management the rent frequently becomes partially and sufficiently closed spontaneously

It was useless to expect union by first intention, as a rule, and, therefore, while the parts should not be needlessly or forcibly drawn asunder, they might be carefully exposed to view each day and made clean by ablution, the urine in the meanwhile being always drawn by a flexible catheter In the secondary operation he prefers the old fashioned one with the quill suture, with the exception that he uses sections of a rather large-sized flexible bougie in place of quills He stated that he does not find the wire suture so easy to introduce or to remove as the silk, and that he has not found it, where the perineum alone is torn, to possess advantages in any other respect If, however, the rent or loss of structure involves any considerable portion of the retro vaginal septum, he would recommend, so far at least as the rectal fissure is concerned, the wire suture, either with or without Bozeman's clamps

In a few extemporaneous remarks which he made after the paper had been read, Dr Hamilton criticised Dr Fordyce Barker's views in regard to the action of chloroform during labor Dr Barker claimed, he said, that the use of this anæsthetic prevented laceration of the perineum, explaining the action in two ways In the first place, he said that it relaxed the muscular fibres of the sphincter vaginæ To him, however, this appeared to be a physical error, not to say absurdity, for when the sphincter was distended to such an enormous degree as was the case when the head was pressing upon the perineum, it was impossible for any constitutional measure, such as the administration of chloroform, to have any effect in relaxing the tension The second explanation was that the uterine action was somewhat suspended by the chloroform, and to that extent relieved the perineum, and Dr Hamilton remarked that this was satisfactory as far as it went, but when the head advanced, this influence would have no effect On the whole, therefore, he regarded the use of chloroform as an unnatural interference with labor

The veteran and distinguished obstetrician, Dr Isaac E Taylor, said that many of the views expressed by Dr Hamilton, were in consonance with his own, although he would take issue with him on some of the points of the paper A great variety of methods had been proposed for the management of the perineum during labor, but, as a rule, they were written clearly, philosophical, or physiological The correct plan was, he thought, to place the fingers entirely back of the perineum, on the space between the rectum and the coccyx In this way direct pressure could be made upon the child's forehead, and the perineum could be saved by delivering the head between the pains Placing the fingers in this situation also enables the accoucheur to prevent rupture of the perineum in occipito posterior positions, by changing the latter to face presentations The shoulders, however, he thought, were much more liable to produce laceration than the head, and great care, therefore, should always be taken in their delivery In regard to the use of anæsthetics, he said he made it a practice to go to his obstetric cases provided with both chloroform and ether He had long since noticed that in a certain proportion of cases chloroform had the effect of putting a stop to uterine contractions, and in these instances he had found that ether almost always had a very happy effect in bringing on the pains again If one of these agents did not answer, therefore, he would try the other, and he generally found that its action would be satisfactory Like Dr Hamilton, he disapproved of the immediate operation, and one reason was that not infrequently the mere effects of labor produced a paresis of the perineum, which gave it an appearance closely resembling a laceration, but which afterward entirely passed away, leaving the part intact

At the meeting of the Academy of Medicine, June 18th Dr H W Mitchell also read a paper on laceration of the perineum In it he gave a report of forty cases upon which he had operated during the past fifteen months, and in all of them he obtained union by first intention In one of the cases the patient was six months pregnant at the time, and the operation was done at her urgent request, on account of the discomfort which she suffered from the rupture She then went on to full term without any unpleasant symptoms, and the new perineum bore the strain of the labor in an entirely satisfactory manner P B P

PRIMARY MALIGNANT DISEASE OF THE KIDNEYS

EDITOR JOURNAL AMERICAN MEDICAL ASSOCIATION

Sir —In my paper on "Primary Malignant Disease of the Kidneys" published in your esteemed JOURNAL, I said, under the head of "Prognosis" "The inferior vena cava being filled with clots in such a great proportion of cases, I am surprised not to find any deaths from embolic processes " After the publication of the paper, Prof W Osler, of the University of Pennsylvania, wrote me that one of his cases referred to by me (p 620, 2d column, line 11 from top) died from embolism of the tricuspid orifice, a sarcomatous thrombus having become dislodged from the renal vein

In the table I also forgot to state that case 16 was one of sarcoma By inserting these additions in the next issue of the JOURNAL, you will confer a great favor on

Yours truly,

GEO MINCES

BOOK REVIEWS

The Student's Guide to Medical Jurisprudence By John Abercrombie, M D Cantab, M R C P Lecturer on Forensic Medicine at the Charing Cross Hospital Medical School, Corresponding Member of the Medico legal Society of New York, etc Sm 8vo, pp xii, 381 Philadelphia P Blakiston, Son & Co, 1885 Chicago W T Keener

The writer tells us in his preface, that this little book was written with the endeavor to condense and group together, in a readily assimilable form, the chief facts belonging to the important subject of Medical Jurisprudence, and that it is not addressed to those who have the leisure to study such standard works as those of Taylor, Tidy, Wharton, Stillé and others Whatever may have been the original intention of the author, he has succeeded in bringing together a marvelous array of useful facts, within the small compass of less than four hundred small pages, and to facilitate reference and study, very full and convenient marginal notes have been added After careful examination of the book, we have failed to find mention of one subject only, that of dynamite injuries, which, in view of the recent interest of the British public in the subject, should have received some notice Under the head of gun-shot wounds, the author has overlooked one of the most interesting cases on record, one reported by Mr Francis Ogston about a year and one-half ago, of suicide by a pistol shot, there being no external wound, the barrel of the revolver was placed in the mouth, and the bullet entering the foraman magnum glanced from the occipital bone to the frontal, and thence back to the occipital, where it was arrested

In dealing with the subject of poisons, all reference to the methods by which they may be detected in organic matters are omitted, which is very proper Analyses are seldom, and never should be made except by competent chemists, and the greater number of works on medical jurisprudence contain just enough information to get the pseudo analyst into a tangle Taken altogether, Dr Abercrombie has given us a very useful little book, and one which will be appreciated by those who wish to gain much information by a minimum amount of reading

MISCELLANEOUS

Vindicated —Recently the secular papers of Washington gave publicity to charges of mismanagement against Dr P J Murphy as physician to the Columbia Hospital, of that city We are glad to notice in a recent number of the *Washington Star* the following decision of the Board of Directors

"*Resolved* That we, the Directors of the Columbia Hospital, in committee of the whole, having granted full and ample hearing to statements criticising the officers and management of the institution, accord to Dr P J Murphy, the surgeon in charge, personally and in his general management, our continued confidence"

Honors —At the recent commencement of the Wooster College, Ohio, the degree of LL D was conferred upon Dr H Z Gill, of Cleveland, formerly of this State

Cholera Precautions in Russia —In view of the danger from cholera the department of the Caucasus has notified the Russian Government that all railways will be furnished with cars containing disinfectants and medicines (flying pharmacies), with corps of medical officers

The Index Medicus —Professor Heischi, of Vienna, has issued a circular calling upon German medical men to support this invaluable periodical, and the *St Petersburger Medicinische Wochenschrift* says that medical men should see to it that it does not fail for want of support.

Professor Richard Volkmann, of Halle, has been raised to the order of nobility

The Mind-Cure —The *London Times* intimates that Boston is responsible for the birth of this latest monstrosity, and says "The saying that extremes meet is never more true than when one of the extremes is transcendental rubbish of the kind that seems to have captivated the good people of Boston" And now comes the announcement that an *International Faith-Cure Conference* was recently held in London Extremes have met—but not in Boston

The New York State Board of Health —The Governor of New York has greatly interfered with the proper working of the Board by vetoing the bill appropriating $15,000 to its use

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JUNE 20 1885 TO JUNE 26 1885

Major Albert Hartsuff, Surgeon, assigned to duty at Ft Hamilton, N Y H (S O 133, Dept East, June 24, 1885)

Major J V D Middleton, Surgeon, granted one month's leave, with permission to apply for 15 days' extension, to take effect about 15th proximo (S O 88, Dept Mo, June 19, 1885)

Captain Blair D Taylor, Assistant Surgeon, ordered from Dept Texas to Dept East

Captain Wm F Carter, Assistant Surgeon, ordered from Department East to Dept Texas (S O 141, A G O, June 20, 1885)

Captain Wm B Davis, Assistant Surgeon, leave of absence extended three months (S O 142, A G O, June 23, 1885)

First Lieutenant R G Ebert, Assistant Surgeon, granted leave of absence for one month, to take effect about July 5 (S O 97, Dept Col, June 17, 1885)

First Lieutenant R L Robertson, Assistant Surgeon, now on leave of absence, is directed to report in person by July 7, 1885, to commanding officer, Columbus Bks, Ohio, to accompany detachment of recruits to Dept Texas On completion of this duty, to rejoin his proper station S O 143, A G O, June 24, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING JUNE 27 1885

Bransford, John F, commissioned as Surgeon on active list, June 16, 1885

Ross, J W, Surgeon, detached from Naval Laboratory, June 30, 1885, and waiting orders

FISSURA ANI, OR FISSURE OR IRRITABLE ULCER OF THE BOWEL[1]

BY ARCHER ATKINSON, M D ,

MEMBER OF THE MICROSCOPICAL SOCIETY OF BALTIMORE OF THE BALTIMORE MEDICAL ASSOCIATION AND EX MEMBER OF THE ACADEMY OF SCIENCES OF MARYLAND

This paper treats of "Irritable Ulcer or Fissure of the Rectum," showing the greater frequency of this and other rectal diseases now than formerly, possibly from the greater facility at our hands for distinguishing such affections, from the habit of keeping statistics of such troubles, from the attention given them by specialists, and from the labors of such special surgeons as Allingham and Ashton of England, and Van Buren, Kelsey and others of New York

2 It includes a brief consideration of the anatomy of the part, as well as some of the reasons why this portion of the bowel is especially subject to such diseases

3 The seat and nature of fissure of the anus are considered

4 The causes producing and keeping it up

5 The analogy between fissure of the anus and of the nipple

6 The usual number of fissures found

7 A consideration of the symptoms and complications

8 Methods of treatment, both medical and surgical

Rectal diseases probably entail more chronic suffering on their victims than affections of other portions of the body Besides being distressing from the pain they produce, they incommode the individual in the ordinary duties of life Nor does it appear that sedentary persons are more exempt from these diseases than others We find the merchant, the minister, the professional man and the laborer about equally liable to these annoyances, in every walk of life we find more rectal troubles than ever before It has been thought they were more common among the better classes, but there now appears no just reason for this supposition The fact is that many persons so afflicted fancy after a few trials of various salves that nothing more can be done for their relief, and settle down to the determination to endure what they cannot help In males these diseases cause sympathetic irritation at the neck of the bladder and in the prostrate gland, while in females they give rise to both uterine and visical derangements as the result of continued straining from piles, with or without fissure

It is a well-known maxim in surgery that rest is the great desideratum in the healing of wounds The difficulty of imposing this rest renders our treatment of diseases of this region tedious, prolonged, and often nugatory For that reason, as from the reluctance of persons to consult us, such affections often reach the chronic state before they are made known to the physician Patients with diseases pronounced incurable, or which drag along for years, are likely to make the round of medical men until they exhaust both patience and resources, not stopping long enough with any one regular practitioner to derive benefit The diseases of the bowel are so annoying that the sufferer will lay hold of any promised hope of cure which assures him of freedom from the torture of knife, ligature, or of caustic It is time there should have been devised some methods of treating diseases of these parts, more encouraging to the patient as appearing less severe than by the plans just mentioned, but while a few cases may and do respond to the "Mild Cure," the greater number and the severer ones must, as before, be subjected to rational and truly surgical procedures Even in the few cases which respond to milder plans of treatment (rather medical than surgical) the time of treatment is prolonged to many weeks and months, when they could in one fourth the time and at half the cost be cured surgically

It is regarded as an advance in the treatment of affections of this region that the necessity for painful operations is less urgent than in what were called the rougher days of rectal surgery In the later treatment of hæmorrhoids is this particularly seen; the injection replacing the ligature, the scissors, the frightful clamp and the actual cautery We know that the rectum stands abuse well,—that even rough handling often does little or no injury, the organ rebelling only by contractions, while by careful manipulation we can educate the part to much tolerance, even to the introduction of the hand, and cases are known in which bottles have been pushed well up into the bowel without injury

The mucous membrane of the rectum is thick, tough, and loosely attached, so as to move about over the muscular layer, as does the lining of the œsophagus. This mucous surface also has folds, varying in size and direction, which allow of distension, whether from expulsive efforts or from the impaction so liable to occur in females. Near the anal orifice these folds are chiefly longitudinal from the folding up of the mucous lining, and it is among *these* that we are apt to find fissures locating themselves.

---

[1] Read in the section on Surgery and Anatomy at the Thirty sixth Annual Meeting of the American Medical Association

The rectum begins at the end of the sigmoid flexure or coil of the colon, and runs about seven or seven and a half inches to reach the anus. This tube lies flattened on itself like other hollow tubes in the body, and is open only when distended to give passage to the fæces, the distension depending on the amount and condition of the excrement, moulded or soft, as the case may be. This fæcal matter should be moulded into a firm mass, averaging ¾ to 1 inch in diameter, yet if hard it may reach 1½ inches, and in proportion to its hardness, its size and the force requisite to expel it becomes one of the factors in producing rents or fissures in the mucous membrane. In diarrhœa, cholera, cholera morbus, and in cholera infantum, we find the stools watery, with little or no fæcal admixture. In cholera the liquid stools like rice-water, consisting of detached epithelial cells. In cholera morbus we have some fæcal matter much thinned out; and in dysentery there is loose fæcal matter mixed with blood, mucus, and hard scybala. In the diarrhœa from taking iron too freely, or from drinking chalybeate waters, there are usually black liquid discharges as the result of the constipation, which is so often the first visible effect of these waters. In bilious operations we find the slate color of the vitiated bile and of the sulphuretted secretions, while the discharges from calomel may be yellow like the yolk of egg, or green, or even perfectly black as tar, or of a slate color. Large doses of turpentine commonly produce black, tarry stools. Bismuth now and then causes black actions, but in some cases we find this mixed with green. Podophyllin usually gives yellow actions, attended by straining and nausea.

The consistence of the fæces ranges from the thinnest to the hard, firm, thick mass, which forms in such as confine their eating to simple bread and meat, without the admixture of vegetables or fruits to give softness to the mass. We find a good illustration in the manure of the horse when fed on oats and mash, or simply on uncut hay and no soft stuff. In the healthy horse fed on hay and grain we notice that as soon as the animal starts off in the morning he is likely to stool, and this is regarded as the sign of a healthy bowel. Such stools then will be firm enough to form into balls from the size of a walnut to that of a small orange. In the healthy man there is usually a more compact condition, with fewer small balls, and a more elongated cylindrical shape. The fæces will depend on the food, thin or solid according to the amount of vegetable or fluid diet, or it may be always solid or liquid according as he is subject to constipation or chronic diarrhœa.

This digression leads us to one of the frequent causes of fissure of the anus, a condition easily becoming chronic, and it is not uncommon to find the perineum around take on a chapped or cracked eczematous inflammation, which runs into the chronic state, to become a source of annoyance both to patient and physician. I am sure I have seen some tormenting cases of pruritus ani proceed just from this condition of things, the crack being in a state of daily irritation from repeated distension after awhile kindles up an eczema with more or less extravasation around, and repeated handling and scratching keep the parts irritated, causing sympathetic irritation at the neck of the bladder, and much suffering. We find now and then a chapped condition of the nates and genitals of infants from contact of urine, but unless this exists just where the skin joins the mucous membrane of the anus, we do not term it "Fissure," nor do we so call the occasional chapped condition behind the scrotum and on the perineum of young boys, which is attended by eczematous itching, lasting usually for months in spite of treatment.

Webster defined "*Fissure*" from the Latin "Fissura," as a cleft, a narrow chasm, made by the parting of any substance, a longitudinal opening. Worcester derives it from *findo*, I cleave, as a narrow opening where a breach has been made, a cleft, a crevice. Nysten, in his valuable French Medical Dictionary, defined "Fissure" as any narrow and shallow solution of continuity of a soft part, but especially is this term given to an *elongated superficial ulcer* which is developed toward the margin of the anus, *between the folds of the mucous membrane*. They often have *hard callous* edges, give great *pain*, and cause *spasm* of the anus." Duhring says, "Fissures are *linear* wounds having their seat in the epidermis or corium. Any portion which is liable to extreme tension may become the seat of fissure." Velpeau describes it as a "small ulcer (Fissure of Anus), straight and more or less elongated, which finds its seat amid the folds of the anus, and which gives rise to sharp pains when the person affected goes to stool." Vidal calls fissure and ulcer one and the same, describing the fissure as a small, narrow, elongated ulcer, a kind of crack, which we find between the folds of the anus, and which is attended by very *sharp pains* in the part. He says the first work on the subject was by Le monverrier, in 1689, of which the title was a "Treatise on Fistule of the Anus," in which the author compares the ulcer to a crack or a chap in the lips and hands, very likely mistaking this condition in his day for fistula.

Mr. Allingham speaks of Fissure and painful Ulcer of the Rectum as the same affection, meaning the ulcer at the rim of the anus and just around it, and not higher up in the bowel. Boyer, in his 10th vol. of "Traitè des Maladies Chirurgicales," published in 1825, mentions this kind of ulcer of the rectum.

There are several kinds of ulcer which may occur at and around the anus, but of the seven recognized varieties we propose to consider only that known as simple irritable ulcer, or fissure of the bowel, and if we touch on other forms it will be merely for the purpose of differentiation. All ulcers here located will cause pain, but true fissure is the most annoying. We know that scrofulous and tubercular diatheses and chronic syphilis all so modify the nature of structures as to enhance much the gravity of any sore. Ulcerations from dysenteric inflammation will not be placed in our list, as such solutions occur higher up in the bowel, as the result of sloughing, to such a degree as bring on more or less stricture from cicatricial repair. Mucous plaques or soft tubercles are, as a rule, too shallow to cause much genuine ulceration, and assume the circular rather than the elongated form of fissure; besides, they are in most cases quickly answerable to the application of the corrosive crystal and to the strong phenol sodique, and melt away like snow on the pushing of constitutional remedies at high doses. Simple ulcers of the anus are almost always traumatic.

It is common for piles to become more or less ulcerated, and this ulceration may end in fissure. Foreign bodies, or fish bones, broken glass, and mineral concretions may all give rise to it. Ulcers here may result from the removal of hæmorrhoids by incision, by the ligature, or by the clamp. Too frequent application of caustics, acid or solid, may give rise to this condition, and indeed where any injury is located about the rim of the bowel it is not difficult for an irritable ulcer to result, and such ulcer here differs from ulcers elsewhere only from the mechanical obstructions offered to their healing. Any sore placed under the same disadvantageous influences might be as painful and just as averse to healing, and the same ulcer will give more or less pain according to the sensitiveness of the part and the contractible efforts of the external sphincter muscle, near or on which it may be located.

When an ulcer is located at or near the juncture of the skin and mucous membrane, it is very difficult to cure, and especially is this true when the orifice is alternately in a state of contraction and distension, as about the mouth and anus. This ulcer then becomes deepened and elongated, constituting a true fissure.

Duhring speaks of the scrotum as liable to eczematous inflammation, where moisture, crusts and painful fissures are prone to occur, followed by extensive thickening and intense itching. It is not difficult then for this same eczematous trouble to extend back along the perineum and reach the anus. The same writer says that fissures often of great size are present (eczema ani), and pain consequently attends each motion of the bowels. Fissures too may occur in pruritus ani, caused by inordinate scratching, chiefly during sleep. It is often difficult to appreciate the great amount of suffering in these cases, considering the slight anatomical lesion which attends it.

As to the frequency of fissure among rectal diseases, Boyer had already seen 100 cases before publishing his work, and Vidal operated on ten cases in 1839 alone. Fissure would appear to rank third among these affections in an analysis of cases numbering 4,000, observed by Mr. Allingham among the out-door patients in St. Mark's Hospital, in London, fistula numbering 1,208, next coming hæmorrhoids, internal and external, 1,065, and third in order he places fissure, or painful ulcer, at 446, that is about ten per cent. This list is taken exclusively from the working classes, yet while the proportion of fistulæ is so large, many ascribe for years their sufferings to hæmorrhoids, when a careful examination would quickly set them right. The masses appear to know but little of such diseases beyond piles and fistulæ.

Any injury about the anus may excite inflammation, which may give rise to abscess or fissure. Bruises are apt to end in fistulous abscesses, but excoriations, whether from excessive horse back exercise or continued riding on hot cushions, the excoriating discharges of leucorrhœa or eczema, or any abrasion long kept up, may give rise to fissure. We have stated that fissures are apt to occupy the base of redundant tissue (tabs), or the base of some hæmorrhoidal tumor, and Ashton mentions a typical case seated just between two such tumors, close up to the external sphincter, and which healed up after the use of nitrate of silver under chloroform in less than thirty days, an unusually brief time. The after dressing consisted of spermaceti ointment, with the extract of belladonna and acetate of lead. He also injected sulphate of zinc solution night and morning after the spasmodic action of the sphincter muscle had subsided. Fissures are constantly showing efforts to heal, but the parts are not kept long enough in repose to admit of such repair, and such as are tubercular manifest no such inclination, but tend to spread in superficies rather than in length.

Ashton thought fissure occurred mostly in middle life and in the laboring man. Vidal says that adults are chiefly subject to this affection, and Boyer had never seen it in infants or youths, and most of the cases seen by him were from 25 to 40 years of age, and some beyond, one case being over 60 years. Mr. Allingham has seen it in the young infant, as well as in old age. He considers it most common in females, while Vidal scarcely ever operated on any except females, probably because of his long connection with the female wards in the Hôpital du Midi, in Paris. Furthermore, we find most fissures occurring in this sex from the fact of the rectum being closely bound to the vagina, so as to prevent laceration in labor. Before Boyer's day this trouble was pretty much ignored, the older surgeons ascribing it to hæmorrhoids, to venereal trouble, and to superficial ulcerations about the parts. Velpeau places fissure at various points, in some cases on the left, and others on the right of the rim, sometimes in front and sometimes in rear, but the favorite seat is at the posterior commissure of the anal opening. Just where the skin merges into mucous membrane is where we are most apt to find the ulceration. Dupuytren made three seats of fissure, however: one just above the lower sphincter, one just below this muscle, and the third just on a level with it, and this last he makes the most painful, and by far the most difficult to cure. In some cases the slit lies below and in others just above the anal ring, and there are fissures which produce nervous accidents *only* when the ulceration actually touches the ring itself.

Blondin supposed that fissures seated above or below the sphincter readily healed, while such as were located on the muscle proper gave most trouble, but Velpeau attaches little importance to this distinction, and has known fissures which had no relation to the sphincter, in any way give rise to great suffering, and some cases are attended by shooting pains down the thighs and the calves of the limb

Usually we find but one ulcer or fissure, but in some cases, even free from syphilitic taint, we may find two or more, as in the case of a lady I recently treated Where syphilitic or gonorrhœal vegetations or syphilitic soft tubercles have existed about the rim there may be any number of shallow fissures-like ulcerations, like soft chancres running, it may be, into quite a long ulcer They have a base more or less hardened, and may even give an indurated elastic feel to the surrounding parts They do not often yield purulent fluid, and may remain superficial for a great while In the lady referred to, the trouble was pruritis ani (itching piles), and three separate fissure-like chaps were found, the longest at the posterior commissure overlapped by a tab caused by repeated scratching, the second was nearly opposite, in front, while the third was about one-half an inch to the left side, just over an indurated mass the size of a small hazelnut She is never troubled with constipation, strange to relate Here there is a case of excoriated perineum with fissure-like abrasions, which are not allowed time to heal before they are made raw again, and they look as if they would cure up in a few days, if left alone They would constitute true fissures if they were seated *nearer* to the rim of the bowel The flabby tabs here keep up a secretion which renders the part soft and liable to crack open Such tabs are apt to be accompanied by fissure of the anus

The causes of fissure in this region are often obscure Moisture alone tends to produce as well as to keep it up, and *itching piles* are likely to be attended by an adjacent ulcer In some patients it is preceded by occasional hæmorrhoidal swellings, which do not attain to the real dignity of a pile, in others true hæmorrhoids after excision leave the chapped or fissured condition, and Thébault mentions a case showing that fissure followed a simple excoriation produced by the awkward introduction of the nozzle of a syringe

Habitual constipation is probably the most frequent cause of this trouble and once set up the part is prevented from healing by the repeated distension and contraction in the natural course of function Diarrhœa and chronic dysentery may produce and keep up the disease Soft syphilitic tubercle may readily extend to and end in a fissure—though this lesion may for a long time remain superficial Nearly all syphilitic patients have these soft tubercles or plaques muqueuses about the perineum—about the nates, beneath the prepuce and body of the organ, as well as just behind the scrotum, and rents and fissures may occur in any of these parts, but they do not occasion the same suffering as the irritable ulcers or fissures of the anus

Velpeau gives the causes of fissure, as constipation, hæmorrhoids, the passage of large hard fæcal masses,—indeed, from anything which excoriates or tears the part superficially, but he also adds that it more frequently arises *without any assignable cause*

We find an analogy between the fissure we are studying and that observed in the nipple of nursing women in the early months of lactation, the nipple becoming tender and aphthous from the flowing milk during the intervals of nursing, from the repeated contact of the child's mouth, and from the forcible dragging of the part in the act of nursing In the case of a lady recently seen, the nipple was so painfully fissured that blood escaped at each effort to nurse the child Astringents did no good—collodion failed entirely, and no relief was afforded until a shield of very thin rubber was put on the nipple to enable the infant to nurse through as well as to keep the part dry from the overflow of milk This precaution failed to promote healing, until, by a happy thought, I wrote for iodoform in balsam of Peru This was applied after cleansing thoroughly with carbolized wash and drying with a bit of soft cotton In a few days the part was free from tenderness and the mother continued her duties as nurse This mechanism of fissure and nipple is like that in the rectum, with the advantage in favor of the nipple, however

We can appreciate the exquisite pain in fissure of the anus when we remember that the nerves of the rectum are many, coming from two sources, viz, from the cerebro spinal system and from the sympathetic,—the cerebro spinal coming from the sacral plexus while the sympathetic proceeds from the hypogastric plexus The lesion being located just among the terminals of these nerves, and on or near the real external sphincter muscle, which surrounds the very end of the bowel, gives rise to the sharpest suffering This muscle lies just beneath the tough skin, and when kept in a constant state of irritation and spasm causes the extreme suffering so much complained of This condition, as before stated, is mostly seen in females, the bowel being closely connected with the back of the vagina by dense cellular tissue

Although we first see the disease as an ulcer, it is likely that it always begins as a simple chap or crack, except, perhaps, in syphilitic cases At first it resembles the chapped condition of the lip in cold, windy weather, but soon takes on the nature and behavior of an ulcer, except that it furnishes but little pus, it is about one eighth of an inch in width, and one fourth or less in length, with its edges at first sharply defined, but soon taking on induration, and the surface may go on extending till it becomes quite a large ulcer In many cases the trouble comes on in an almost insensible manner, the first notice of it being a slight itching with little or no pain, some heat, and a sense of crawling This may last for a year or even longer before actual pain sets in In other cases it attains its worst form in a few weeks All fissures are not equally painful, some being so only at intervals As a rule the longer and deeper the fissure the more painful it becomes

We now and then find vegetations in gonorrhœal women, giving rise to an acrid discharge, which moistens the perineum and keeps the anus bathed in pus and more or less chapped In true syphilitic abrasions the itching is less This condition yields to snipping off the vegetations, or to calomel powder, or to touching with the bichloride crystal Tabs from old external piles keep up a moist condition about their base, and it is here that we are likely to find fissure located, as seen in the case of a gentleman, aged 87 years, who has now the remains of a large fissure on the left anterior portion of the rim of the bowel It is difficult to say what initiated it, but for many years his habit was to strain violently at stool, and to spend half an hour or more on the commode A year ago this fissure became very painful The bowels were kept soft by gentle laxatives, and an occasional injection of tepid water or a soft suppository, the part being gently washed with a soft sponge and dried after each operation, and a little iodoform ointment being placed within the folds This becoming objectionable, a two grain wash of carbolic acid was substituted This fissure is now entirely healed There were two tabs, the fissure lying just beneath and to the side of the larger one Many years before this patient had suffered from external piles, which, suppurating, left the tabs mentioned

Another patient from a distance had three large hæmorrhoids, attended with great prostatic trouble and annoying prolapse of the bowel The fissure which had existed two years before had been cured by injections of krameria, he said, at last there remained no trace of it Two of the hæmorrhoids were so much reduced by treatment, and the prolapse and prostatic trouble so completely relieved that he went home satisfied for the time In this case there were fleshy growths which kept the parts continually moistened and the large hæmorrhoid caused annoying prolapse of the bowel The hæmorrhoids were destroyed and the prolapse cured by injections of strychnia Ashton mentions a typical case of fissure seated between two hæmorrhoids, which healed in thirty days after the use of nitrate of silver

Symptoms—At first the patient experiences some heat and smarting at the moment of defecation, the harder the mass the greater the smarting It is not always at this time that these sensations are worse, but for an hour or more the patient dreads the return of the pain He knows from experience how it will be, defers the evacuation until the habit of costiveness is contracted, when he experiences absolute pain at each effort This may go on for months and years until life will become a burden The patient, dreading the consequences, eats but little, till he loses strength and looks as one with some severe organic disease He, at first, imagines that he is chafed or that he has slight piles Often at the end of a few days these symptoms may disappear if he is careful as to cleanliness and costiveness This relief is but temporary, soon the heat and smarting return, the uneasiness continuing for a longer time, the stools being now and then streaked with blood and some pus Some comfort is now derived from mild laxatives, from clysters, and from a cooling diet Soon these measures lose their effect, and the disease goes on steadily increasing Some have to resort to aperients every two days, with now and then an injection If he goes several days without an action he describes the pain as that of a heated iron being passed into the bowel He feels a convulsive contraction, and even spells of fainting, and the finger introduced into the rectum meets with spasmodic contraction of the sphincter, which is kept irritable all the time These pains are not the same in all persons, and even in the same patient will vary in kind and intensity

After the stool there remains more or less lancinating pain and even pulsation, as though the part were about to gather Boyer once saw a female who had fever after each action Violent exercise, sitting on hot cushions, and the drinking of wine, all augment the suffering Velpeau mentions a case in which the patient said he would rather die than have another action of the bowels In some females the suffering increases at each menstrual period The pain once begun is increased by each motion of the body, some are unable to sit up, while others can scarcely lie down in bed The pain is augmented by the presence of fæcal matter in the rectal pouch Even liquid stools excite pain and Boyer cites the case of a patient who suffered even during the passage of flatus The degree of pain varies with the susceptibility of the person and with the location of the sore on a nerve branch or on the sphincter Boyer contended that this spasm of the sphincter caused the fissure, and that incision of this muscle without touching the ulcer at once quieted the pains, but Trousseau claimed, as did Velpeau, that the fissure is the original lesion, and serves to keep up the spasm of the sphincter

The two most constant attendants on this trouble are the spasmodic contraction of the anus, and the sensation of burning, while the presence of the ulcer may be wanting, in such cases an incision into the part has afforded prompt relief Again, there may be one or more small ulcers which cannot be found, but which cause pain on passage of the fæces over them Mr Allingham cites eight cases in which there was spasmodic contraction without *any* fissure at all The suffering may be due partly to the erectile nature of the skin and mucous membrane just at the verge of the bowel, as well as to density of fascia

To recapitulate, then, the symptoms of irritable ulcer or fissure of the bowel, there are severe, smarting and burning, sharp pains, continuing for an hour or longer, spasmodic contractions of the external sphincter muscle, with a narrow elongated fissure, or irritable ulcer, generally shallow, at the end of the rectal tube We may find just the smallest amount of pus, but commonly the torn part has the bright red color of fresh beef, except that we sometimes find a grayish coat along its base or floor

The diagnosis is mainly effected by sight and by the touch When the chap cannot be seen, we may suspect its presence by the touch, the finger in the rectum detecting an irregularity at a certain point, or producing pain enough to cause flinching, the finger encountering a sharp constriction by closure of the ring, this is one of the main distinguishing characteristics of the presence of fissure The returning finger is often streaked with a little blood or pus The moulded stool may have a trace of bloody pus on the side on which the fissure is located The contact of the finger or probe gives exquisite pain Straining often reveals the presence of the fissure without further examination

To obtain a good view, it is best to pull aside the buttocks so as to open the anal ring and direct the patient to strain the bowel having been previously cleaned out by a cold water enema In some few cases we may see the lower end of the ulcer without even this precaution In others we will find no ulcer at all It is not often that we need the speculum to bring the lesion into view When we find the patient flinch and cry out with pain, when the finger is very gently introduced, and the sphincter closes suddenly and tightly, we may be sure that there is a fissure

The distinguishing signs of fissure, then, are 1 The violent contraction with pain of the sphincter muscle, 2 A burning pain at the moment of expulsion of the stool and just afterwards, 3 A superficial ulcer, narrow and long, just at the entrance of the bowel These three circumstances are sufficient to form a diagnosis In making examinations in painful cases, or in process of dilatation or incision, we may profit by the anæsthetic action of the hydrochlorate of cocaine, a few drops of the five per cent solution being rubbed in and around the parts, and allowed to remain for fifteen minutes before beginning our manipulations, the action of this agent being slow on the rectal mucous membrane

Along with fissure may exist wart like excrescences and hæmorrhoidal tumors, though they are by no means necessarily present Again, a hæmorrhoidal tumor just above the external sphincter muscle may become ulcerated about its base, and this small ulcer becomes continuous with the outer surface, keeping up painful spasmodic contraction In every case of fissure the anus and the parts around it may sympathize to a greater or less extent, especially in old cases Howe once mistook a fissure for an enlarged prostate gland from the great amount of lymphatic irritation set up in the vicinity Retention of urine and difficult micturition have been noticed, and now and then the whole nervous system is affected, the sufferer relapsing into a melancholic state Patients often complain of the sympathetic disturbances, forgetful of the pains about the rectum proper, or may refer them entirely to hæmorrhoids which may not even exist, while the physician directs his remedies to the relief of the remote trouble Vidal mentions one case in which a woman referred all her sufferings to the jaw, experiencing the same rigid stiffness as in true trismus

The treatment of fissure of the rectum may be divided into medical and surgical There are now and then cases which get well with no treatment at all, and which cause but little inconvenience, and it is mainly to this class that we look to the action of medicines to afford relief Others may heal up without applications or operation, and yet for years produce much suffering Two cases are cited, which lasted, one for three years, the other for five years, both ending in perfect cures without any interference whatever Ashton asserts that in most cases, in the early stage, an operation is not successful, and reports several cases of cure without such resort He lays great stress on lead water and opium, and cites the case of a fissure occurring to a man at stool, which cured in 18 days without surgical interference Dr Parker, of Richmond, Virginia, writes me of two cases cured simply by confining them to rigid fluid diet, and Velpeau gives the case of a medical student who suffered for eight years with fissure, which cured up without any treatment Boyer cured cases with an ointment made of leek juice, mulberry juice and the oil of sweet almonds Of this he would inject a little into the bowel each day Velpeau cured several cases with the ointment of ammoniated mercury

In any plan of treatment perfect cleanliness is all important, the patient being especially careful against rough handling He should dry the part by patting with a soft linen or a velvety sponge One of the mildest applications would be the simple or the benzoated ointment of the oxide of zinc, into which the aqueous extract of opium has been incorporated, or to this may be added equal parts of Hebra's ointment of litharge, very finely rubbed down Allingham's ointment, consisting of calomel, extract of opium and of belladonna, rubbed up with the ointment of sambucus or elder, is also useful The gentlest handling should be exercised in these cases The pile ointment of Prof N R Smith, of Baltimore, is also useful, and indeed is soothing in pruritus ani, with or without fissure Lead washes give temporary relief with or without the extract of opium Occasionally the solution of nitrate of silver does well to stimulate the indolent base of the fissure, provided the bowel be first emptied above and below, and then well splinted with opium, and the patient be kept on fluid food An ounce injection of cold water with 40 drops of tinct opii and a little starch will wonderfully assuage the sufferings from spasm of the sphincter, cautioning against contracting the opium habit, for the relief afforded is so great that the patient is attempted to repeat it each night Two things should be insisted on in beginning the treatment Regulation of the bowels and perfect cleanliness of the part To accomplish the former some measures must be adopted to secure a soft action each day Some prefer the morning for this, but night is the best time, as the patient may bathe and anoint, and then be quiet

Often an anodyne suppository is very useful, containing two grains of the watery extract of opium, or the same with two to five grains of iodoform and balsam Peru If the patient is robust it is well to open the bowels with the pil hydrarg, or the mild chloride, in dose sufficient to arouse the duodenum and gall bladder This may or may not be followed by castor oil mixture Once the motions are softish it is quite easy to keep them so with the compound liquorice powder, the electuary of sulphur or of senna, by the Buckthorn cordial, the cascara fluid extract in gentle doses, or by the saline aperients or any of the purgative waters, of which so many are now on the market Unless we have to deal with a fissure resulting from secondary syphilitic abrasion, the constitutional action of mercury is not to be thought of

It is wonderful how a cold water injection now and then lessens the occurrence of spasm of the bowel by aiding the passage of fæcal matter, which, without the injection, would remain hard and distend the tender part Besides, the tonic action of the cold water does good itself Care must be taken, however, not to destroy the tone of the bowel by injections Sometimes warm, again cold, ablutions will give most relief to the pain Mr Ashton praises an ointment composed of gr xi of acetate of lead, ʒi of extract of belladonna, and ℥i of spermaceti ointment, as well as an ointment of the oxide of zinc and extract of belladonna, applying them on a bit of lint, and gently packing it into the fissure When the fissure is due to or is kept up by an ulcerated internal hæmorrhoid the only hope of relief is to destroy the pile The extract of rhatany (krameria) has long been reputed a curative agent for fissure, on account of its astringent properties It appears to restrict the flow of blood to the irritable part, and thus to promote healing, ʒi of the extract may be dissolved in ʒv of water, and this used as an injection night and morning, the patient retaining the injection as long as possible The extract of rhatany rubbed up with water was a favorite application with Nelaton The fluid extract, either pure or mixed with glycerine or ergot, is often used as an injection Gibson used injections of rhatany and caustic applications with success

Dupuytren successfully used an ointment made of extr belladon ʒij, lard ℥ij, honey and water, aa ℥j, this was introduced into the bowel by means of a mop, the size of the mop being gradually increased until the resistance of the sphincter was overcome The pain is quite severe at first, but soon ceases Velpeau said that when medication failed, the most efficacious measures are cauterizatian, dilatation and division of the sphincter and excision of the ulcer Nysten claims that cauterization with nitrate of silver should always be tried before the resort to the knife, the caustic should be applied thoroughly to the bottom and sides Beclard claims to have succeeded with this plan in all cases, though other operators have been disappointed by it The stick caustic acts, as does the heated wire, by changing the irritable ulcer into a simple fresh wound

Simple dilatation of the anal orifice has given good results in very many cases Dubois, of Paris, always succeeded with this, plan but the process is long, tedious and painful Velpeau found that it succeeded well with or without the use of ointments Boyer suggested division of the sphincter as the best and only method of curing fissure of the anus, a plan which is now followed by the greater number of surgeons In some cases he cut through the fissure, in others to the right or left, his theory being that the constriction caused the fissure and not the fissure the constriction He first emptied the bowel by injection or by a mild purgative, so that the patient would not be called upon to go to stool for a few days, and then cut entirely through the thickness of the sphincter muscle Some surgeons have modified this method by cutting only through half of the muscle, which seems to have the same good effect without the risk of causing paralysis of the bowel Syme conceived the idea of cutting through the base of the fissure, thus relaxing the part without causing paralysis of the bowel, leaving the greater portion of the muscle undivided Velpeau recorded two cases which died from section of the sphincter A few cases recover after forcible dilatation with the thumbs, but the tearing process is to be deprecated as cruel practice

Etherization of the rectum might be resorted to in these cases in order to facilitate dilatation just short of actual tearing, the rectal pouch being brought under the influence of the ether sufficiently to thoroughly benumb the part Rectal etherization has been followed by death, however, and the same object may be attained by using the five per cent solution of cocaine But whatever plan of treatment be adopted, the patient should, when practicable, call each day at the surgeon's office

If the ulcer is to be divided, a blunt pointed bistoury should be used, with a very sharp cutting edge, it should be placed vertically in the base of the ulcer and firmly pushed forwards or backwards, the part being kept moderately tense so as to facilitate the division of the muscular fibres The base of the ulcer may be thoroughly transfixed from below with the sharp point of a keen curved bistoury, and cutting upwards so as not to wound the opposite side of the bowel Should the fissure be located in the anterior commissure, great care should be taken not to injure the bulb Redundant tabs and polypoid growths should be removed in order to lessen the irritation and moisture, which serve to keep up the fissured condition

A suppository of the watery extract of opium with the extract of rhatany will serve to alleviate pain after the operation, and will assist in promoting healing, As with other ulcers, iodoform, with or without opium, made into suppositories with balsam of Peru and coca butter is of good service Tannin, iodoform and balsam of Peru also make a useful suppository for promoting healing Absolute rest should be enjoined so long as the means of the patient will allow When an opportunity offers, I shall use iodoform with collodion and opium hoping to hasten the healing process by the first, and to prevent reopening of the fissure by the second

The advantages are to be gained by excision are In not injuring the sphincter muscle, in not causing much of a wound, and in requiring only rest with a simple dressing to insure speedy healing

To recapitulate, then, the essentials for successful treatment of irritable ulcer of the rectum, there should be perfect rest of the bowel and of the entire body, when possible, for the few days necessary for the cure

Sound sleep should be secured by the use of opium, administered either by the mouth or hypodermatically, or preferably by an opium suppository each night When it is necessary that the bowels should move, the action should be facilitated by a cold water enema, containing laudanum if required, to wash out the mass and give tone to the parts The food should be such as will cause but little roughness in the bowel, and which will not produce fæces of such mass and consistency as to cause distension and tearing of the healing fissure

A CASE OF ACUTE PELVIC ABSCESS, WITH REMARKS[1]

BY WILLIAM WARREN POTTER, M D,

OF BUFFALO NEW YORK

Mrs B——, aged 38 years, twice married, and three times a mother from her first marriage, was seized with pain in the pelvic region on the night of March 17, 1884 I saw her first two days afterward, March 19, and found her suffering with intense pain low down in the abdomen, but particularly in the region of the right ovary, where the tenderness upon pressure was extreme The abdominal muscles were tense, the lower extremities were flexed, there was constant nausea, and micturition was difficult or impossible An examination, *per vaginum*, was made with difficulty because of the pain which it excited or increased, but the uterus was found low down in the pelvic cavity, with a patulous os, and the right ligament was very tender Bi manual palpation was attempted, but could not be satisfactorily employed by reason of the suffering which it inflicted Temperature 101 F, pulse 110 The patient had been consulting a so called clairvoyant doctor for some time previous to the date of my first visit, from whom she received advice for a supposed ovarian "trouble" This person prescribed "cotton root and gin," and Mrs B—— had taken two pints of this mixture during the two weeks prior to the illness we are considering, but of what strength I was unable to ascertain

Treatment Hypodermic injections of morphia and atropia hot fomentations to the abdomen, the hot vaginal douche by Foster's apparatus, and catheterization when necessary Quinine in antipyretic doses was administered per rectum The pain increased, or was only held in partial abeyance, during the succeeding few days, nausea and vomiting were uncontrollable, while the temperature continued to rise slowly, and the pulse ranged from 110 to 120 per minute Daily examination, *per vaginam*, disclosed an ever increasing fullness or hardness of the pelvic tissues and organs—visceral impaction—while the uterus was being gradually lifted up and pushed forwards under the pubic arch There had been slight rigors previously, and on the night of the 26th, one week after my first visit, there occurred a decided chill Next morning, the 27th, I found fluctuation behind the uterus, and deciding that an abscess was undoubtedly forming, I asked a consultation

In accordance with my request, Dr Thomas Lothrop saw the patient with me on the afternoon of the 27th, and confirmed the diagnosis of perimetric abscess At his suggestion we deferred surgical interference until the next day On the 28th she was placed under ether by my son, Dr F H Potter, and, with the assistance of Drs Thomas Lothrop and W S Tremaine, I drew off, with the aspirator, more than three pints of fetid pus, from an abscess occupying the field of Douglas' pouch The needle —a large one—was passed up behind the cervix and thrust through the vaginal vault in the median line After the abscess was evacuated the incision was enlarged with a bistoury, the aspirator needle serving as a guide, a drainage tube inserted, and the cavity washed out with mercuric chloride water, 1 to 3000

The condition of the patient after the operation was not favorable, she was emaciated, pulse 120, temperature 102° F, tongue dry and furred, with red margins, but the pain ceased almost immediately She was fed on iced champagne, which was the only medicine the stomach would retain, nourished by small enemata, and catheterization was continued On the 30th, two days subsequent to the operation, during my evening visit, I thought she was dying, the pulse was no longer perceptible, and she lost consciousness for a time, but rallied again under the hypodermic use of ether, brandy and alcohol, which were successively and rapidly administered

The pus cavity was washed out several times a day, first with the mercuric solution, 1 to 3000, and then with 2 per cent carbolic water This for the first five days after the operation, or until the 2d of April, then, finding the character of the discharge did not improve, but still retained the same dirty brownish color and fetid odor which it possessed at first, I began to cast about for a plan by which iodoform could be introduced into the cavity Noticing about this time a device by means of which Dr David Prince, of Illinois, carried this drug into the bladder in the treatment of cystitis, I prepared an emulsion of iodoform with starch according to his formula, and, after first thoroughly washing out the cavity, injected this iodoform emulsion into the abscess sac, retaining it there with a pine plug fitted into the mouth of the drainage tube From this time, day by day, the improvement was marked, and of a most satisfactory nature, the size of the cavity rapidly diminished, the quantity of pus correspondingly lessened, its fetid odor disappeared at once, the physical condition of the patient improved with amazing rapidity, so that by the 9th of April, twelve days after the operation, the cavity was closed and the drainage tube withdrawn Two days later the temperature and pulse were normal as to degree and rate, and buccal ingestion was resumed The patient remained under observation until May 1, when she was considered well except as to strength and flesh, but, in a few weeks more, these were entirely regained

The above synopsis is made from very full notes of the case, and though many details are, for the sake of brevity, omitted, it is yet believed to present all of its more important features Two competent nurses, one a graduate of a training school, were in constant attendance as long as their services were required, and to their faithful, intelligent, and untiring care is due, in a large measure, the successful issue here recorded

This case is not presented to the Section because of the novelty of the disease, nor yet because of any special claim to skilful or unique management in its conduct, but rather because it represents a form of disease with which we may, with propriety, become more and more familiar through frequent discussion, particularly as text books, for the most part, afford us meagre guidance in the matter Permit me, therefore, in passing, to mention one or two features of this case, which impressed me at the time as meriting thoughtful attention.

---

[1] Read in the Section on Obstetrics and Gynecology at the thirty sixth annual meeting of the American Medical Association

1. The rapidity with which so large an abscess formed, in the non-puerperal state.
2. The enormous quantity of pus found, and drawn off at the time of the operation.
3. The corresponding rapidity with which it filled by granulation, and finally closed.
4. The introduction of iodoform into the cavity, and the rapid changes which were apparently due to its use.
5. What part did the cotton root play in the causation of the abscess?

That the subject of pelvic abscess is engaging the attention of the profession at the present time more than at any preceding period, is apparent to every one who is at all familiar with its history. This is largely due, no doubt, to the fact that we have come to understand the value of drainage, and the frequent washing out of pus cavities with antiseptic liquids, by which methods better results have been obtained than was formerly the case. The diagnosis, too, is more readily made since the Sims' position, bi-manual palpation, and the aspirator needle have come into vogue. The cellular or connective tissue which fills the space intervening between the several pelvic organs is peculiarly exposed to the dangers of inflammation. These organs, to begin with, are very mobile, subject to various degrees of expansion and contraction, according as they are distended with normal or abnormal contents, or are suddenly, and mayhap violently, emptied of the same. Then, from without the body they suffer, not infrequently, from various vicious practices which are resorted to for the purpose of preventing conception, or possibly, interrupting its progress when it has already taken place. Again, cold water injections are made use of preceding and following, nay, even during menstruation, by a great number of women. For these and various other reasons, which I need not now take time to enumerate, the pelvic connective tissue seems especially liable to take on inflammatory action known as cellulitis. Suppuration is only one way in which it may terminate, though by no means is it an uncommon one.

A great impetus has been given to the study of diseases of the pelvic cellular tissue by the researches of Emmet, his published writings on pelvic cellulitis have, indeed, become classic. He was the first observer, so far as I know, to boldly assert that the diseases of the uterus and its appendages, in the non-pregnant state, which most writers regard as beginning primarily in those organs, really have their origin in the pelvic connective tissue as an etiological base, and are transmitted secondarily to the womb, ovaries, etc., in the form of metritis, ovaritis, and the various modifications of these maladies. Even a hasty glance at the anatomical peculiarities of the pelvis, with reference to the blood and nerve supply of the viscera, would establish a reasonable basis for this belief, for it will be observed that the blood vessels and nerves of the pelvic connective tissue are distributed with a lavishness which is not equalled in the same given space in any other locality. Furthermore, the uterus is nourished by blood which is received through the areolar tissue, its nerves, likewise, reach it through the same avenue. These vessels and nerves are doubled upon themselves and interwoven into meshes, until one, in attempting to trace them, becomes almost lost in the mazy labyrinth of vessel and fibre. This arrangement is wise in that it permits the necessary mobility of the organs, as well as the traction incident to gravidity, and displacements of the womb, without impinging upon the calibre of the vessels or rendering them tense, but it becomes an element of weakness in pathological conditions of the pelvic viscera, in the permission of great blood stasis. It is, therefore, easily understood how pelvic blood-stasis plays such an important part as an etiological factor in uterine disease, and in disorders of the subjacent organs and tissues.

These maladies, for the most part, in the non-pregnant woman, have their commencement in an undue fulness of the vessels of the connective tissue. The nidus is, perhaps, a trifling irritation, then arterial pressure is increased—the flux begins, there is next dilatation of the arterioles—tone is lost, the equilibrium between the venous and arterial systems is no longer maintained—there is venous engorgement, the nervous supply becomes deranged—there is nerve turmoil, in short, there is true blood-stasis. From blood-stasis to congestion is but a step, and then follow, in the natural order of sequence, the various phenomena of inflammatory action, which, if not arrested by prompt measures, frequently result in the formation of abscesses in the pelvic connective tissue. The formation of pus follows the breaking down of the lymph exudate or serum, which are the primary products thrown out by nature for her own protection, and this transmutation may be regarded as an evidence of dyscrasia. A number of small collections of pus are liable to coalesce and form an abscess, and this accumulation most frequently occurs directly behind the womb, or a little to one side, along the track of one or the other of the broad ligaments. Abscesses sometimes form in the substance of the ovaries and Fallopian tubes, a complicated form of pyo-salpinx, in which these organs have undergone complete degeneration.

The treatment of pelvic abscesses need not engage us long. The several methods which have been recommended will readily fall under one of two heads, viz.: the expectant or conservative plan, and that by evacuation, or the radical method. The expectant treatment was the method of yesterday, the treatment by evacuation is the system of to-day. Here, as elsewhere, pus is an enemy to the human body which should be gotten rid of as soon as possible after its existence is ascertained, and its locality defined. The late Professor Brickell, of New Orleans, has even taught that collections of serum in the pelvis should be promptly evacuated, lest they continue to incite pain, inflammation, and otherwise ravage the pelvis. If left to themselves, these abscesses may rupture into the posterior vaginal cul de sac, or into the rectum, or, less frequently, into the bladder. There is also the remote danger that they may rupture into the peritoneal cavity, when there is almost sure fatality resulting This accident has happened more than once, and Thomas, in his treatise, relates that it did happen once to Sir James Y Simpson, who postponed a proposed operation for evacuation one day too long There is but one favorable channel known to me whereby pus may escape spontaneously from the pelvic cavity, and that is *per vaginam* If we could be assured that nature would rid herself of the accumulation through this avenue, it would still seem to be within the province of good surgery to interfere reasonably early, in order that the dangers of septic absorption might be avoided But experience has sadly taught that this is almost the last route sought, when nature is left to her own resources The greater probabilities seem to tend in the direction of the rectum, bladder, abdominal parietes, or that the pus may burrow in almost countless directions among the intra-pelvic viscera, and that finally the patient may become exhausted through septic absorption, without its having made exit at all No, given a case of well-defined pelvic abscess, and we may not hold off our hands a single moment, after we are confirmed in our diagnosis, without infinite jeopardy to our patient, and greatly increasing the burden of our responsibilities

The method of the evacuation will be determined by the nature of the case in hand The trocar and canula, the aspirator, or the groved needle, have each served for the purpose of operating through the vagina, and may each have their place in the accomplishment of good work The principal thing to be borne in mind is that the pus cavity is to be thoroughly emptied, then thoroughly cleansed, and a good opportunity afforded for thorough drainage afterwards If either of these instruments is used, the opening should be incised, or better still, dilated to an extent which will permit the introduction of a drainage tube sufficiently large to meet the requirements of the case, after the pus is drawn off Antiseptic liquids must be thrown into the cavity through the tube, sufficiently often to keep it orderless and clean, and and for this purpose I have found a glass syringe, holding two or three ounces, the best instrument This part of the work cannot be intrusted to another, the surgeon must do it himself I lay great stress upon this dictum If the abcess cavity be large and the walls as a consequence quite thin, there is danger in the use of much force in making the injection, lest they rupture Even a very competent nurse cannot be trusted with this delicate duty No one is so familiar with the topography of the abscess and its surroundings as the operator, whose delicate touch has explored the field so many times, and he alone must perform this important, though irksome, service for the first few days, at all events Moreover, there must be no uncertainty as to the frequent cleansing of the cavity, in the most thorough manner possible, and if he does it himself, he may feel sure that it is well done

In the treatment of chronic abscesses of the pelvis, Byford reccommends the use of the curette for the removal of certain pathological formations which hang from the walls of the cavity, oftentimes, and prevent or delay recovery This would seem to be a most excellent expedient for the class of cases in which he uses it, for such abcesses are prone to recur unless radical precautions of that nature are adopted When the abscesses cannot be readily reached through the vagina, but can be easily discerned above the pelvic brim, the abdominal section affords the safest method of evacuation This may be done in accordance with the method of Mr Lawson Tait, who opens the abdominal wall, stitches the sac to the margins of the incision, and after opening and cleansing it freely, treats it with the drainage tube in the usual way

A little while ago and he would have been considered a bold surgeon, if not a rash one, who would invade the pelvic cavity with a knife in search of a pus cavity, for, it must be conceded, that there are few localities of the body where it is more hazardous to cut than this The aspirator serves to reduce the operation through the vagina, surgically speaking, to one of minor degree Not so with the operation of Tait, which must be done with all the precautions, and skilful judgment which belong to the abdominal section for any purpose The great difficulty in executing Tait's operation, seems to be found in those cases where the abscesses are small and are situated well down in the cavity of the pelvis, for in these, it is oftentimes difficult to suture the abcess sac to the peritoneal margins of the incision

The improved methods of diagnosis and treatment of the diseases of the pelvic cavity in women, constitute one of the greatest glories of medicine in the nineteenth century The benificent influences which have arisen, and which will continue to the end of time to grow out of the one operation for the relief of cystic disease of the ovary, are not within the pale of human computation, and, when we reflect that this is but a tithe of the blessings embraced in the whole field of abdominal and pelvic diseases, which have been placed within the domain of surgical cure or relief, during the period mentioned, then indeed may we truly say, that the colossal labors and achievements of the gynecological surgeon place him in the front rank among the benefactors of the race

306 Franklin street, April, 1885

A CASE OF TRAUMATIC ANEURISM OF THE AXILLARY ARTERY, LIGATION OF THE SUBCLAVIAN, SUBSEQUENT INCISION OF THE SAC, FOLLOWED BY RECOVERY, WITH REMARKS[1]

BY L S McMURTRY, A M, M D,

OF DANVILLE KY

In order to place within easy reach of the statistician a case illustrating some important points in pathology and treatment, involving operative procedures of gravity and importance, I submit the following report of a case of axillary aneurism

On the 20th day of last November M C, a robust man, accustomed to out door life on the farm, called at my office for examination and advice His age was 30 years. He possessed a good constitution and powerful muscular development. He gave the following history: Thirteen months before, he received a pistol wound, the ball entering the right shoulder in front, imbedded itself in the vicinity of the joint. The wound healed promptly, with but little constitutional disturbance. Several weeks afterward he observed "a lump" in the axillary region, which increased in size from week to week. At the date indicated—20th of November last, thirteen months after receiving the pistol wound—the tumor had reached the dimensions of a newly born child's head. The pressure upon the brachial plexus of nerves had paralyzed the arm, forearm and hand, so that this member hung powerless at the side, possessed of very limited degree of motion, and much wasted by disuse. The diagnosis, aneurism of the axillary artery, was evident on inspection, and was made absolute by the thrill under palpation, and the bruit upon auscultation. That it owed its origin to a wound of the axillary artery was evident from the history, and the scar of the pistol wound upon the skin. A thorough examination showed that the tumor had burrowed beneath the pectoral muscles after occupying the entire axilla. The walls were thin, and moved to and fro with every pulsation of the heart. The radial pulse was small in volume, and fluctuating.

---

[1] Read before the Kentucky State Medical Society June 24 1885

On the following day but one, I proceeded to ligate the subclavian in the third part of its course. The patient was anæsthetized by Dr. R. W. Dunlap, and Drs. Geo. Cowan and Fayette Dunlap assisted me during the operation. The incision was made above the clavicle, and a dissection made through the supra clavicular triangle of the neck to the first rib. It became necessary to divide the external jugular vein, after tying it. Some difficulty was experienced in finding the artery in its home on the first rib, the vessel having been drawn from its groove by the ever increasing axillary growth. The aneurism needle was passed, and a strong silk ligature applied to the vessel just at the external border of the anterior scalenus muscle. The pulsation ceased in the tumor as soon as the vessel was compressed. The wound was closed in the usual manner, and the ends of the ligature were left hanging from the wound. The radial pulse was annihilated, neither was any pulsation detected along the course of the brachial. The arm was enveloped from shoulder to fingers in cotton wool, and a flannel bandage applied.

The progress of the patient was uninterrupted by either accident or complication. A few hours after the operation the hand and arm became prematurely warm as a result of the increased activity of the superficial capillary circulation. On December 13, the 21st day after the operation, the ligature came away, the wound having promptly healed. The tumor became firm after the operation, and at the time the patient returned home—one month after the operation—was very perceptibly decreased in size. Six months after the operation on the subclavian, the patient returned to me for further treatment. The tumor remained large and elastic, and though he had in limited degree regained the use of his arm and hand, he was unable to pursue his occupation. I at once determined to incise the sac and turn out its contents. The circulation in the arm and hand was excellent, and a small radial pulse could be detected in the affected arm. There was no pulsation whatever in the tumor from the moment the ligature was applied to the subclavian. The pressure on the brachial plexus of nerves was the sole cause of the remaing trouble. The second operation was done at the patient's home in Mt. Vernon, Ky., in the presence of Drs. Brown and Lovell of that place, Dr. Hugh Reid, of Stamford, and Mr. Worthington, of Danville, a medical student. Having made an incision over the entire length of the tumor, I threw a ligature around the axillary artery on the distal side of the tumor, and incised the tumor. The cavity was filled with a soft arterial clot, which was scooped out and the cavity washed out. During this second operation I was enabled to appreciate for the first time the full extent of the tumor. It penetrated the entire depth and extent of the axilla, and had burrowed freely beneath the pectoral muscles. This wound was closed and dressed in the usual manner, with free drainage space. The pressure now being removed from the brachial plexus, the arm and hand are rapidly regaining their power, and the patient will soon resume his occupation. In the second operation it was evident that the vessel was completely closed by the first operation, and the tumor received no collateral or recurrent supply from any source. The artery above and below the tumor had become a fibrous cord.

Concerning the operation of deligation of the subclavian it seems pertinent here to record a few observations suggested by this case. The operation varies much in difficulty. When the patient is thin and the parts adjacent are normal, the operation is as easily executed as upon the cadaver. When, however, the clavicle is greatly curved, as in persons accustomed to manual labor, and the patient stout and muscular, it is *quite different*. In these latter circumstances the artery lies at the bottom of a deep cavity, constantly filled with blood from the many small vessels of necessity divided in the dissection. A very limited experience with the operation will suffice to convince one that such an operation must require time, and may easily terminate in disaster on the table. So skillful an operator as Dupuytren occupied one hour and forty minutes in the operation, and, in one case, found at the autopsy that the needle had been thrust through the artery and included one of the large nerves of the brachial plexus with one-half the artery. And again, in a case of Dr. Warren, of Boston, the air rushing into the chest during the operation demonstrated that the pleura was punctured.

The anatomical conditions surrounding the seat of operations will serve to explain the frightful mortality after ligature of the subclavian for axillary aneurism, and the frequent failure to secure complete cure. Although embodying the principles of the Hunterian operation, it is not far removed from Anel's method. Indeed when, as in the case reported, the aneurism extends above the acromial thoracic branch, the circulation through the sac is completely arrested. Dr. Wyeth's tables embrace seventy-five cases in which the subclavian was tied in the third part of its course for axillary aneurism, with a death rate of 37 per cent. Mr. Bryant records 21 cases, of which 9 recovered and 12 died. Of 48 cases occurring during our late civil war, 37 resulted fatally, a mortality of 77 per cent. It need scarcely be stated that secondary hæmorrhage is a conspicuous cause of death.

It is important to note just here that these statistics, showing such severe mortality, include both idiopathic and traumatic aneurisms. The case I have reported is an illustrative one and the type of a class, a circumscribed traumatic aneurism resulting from a wound of the external tunic of the artery. Such cases usually occupy several months in development—the one described above occupying thirteen months, and the aneurism is provided with a well defined and firm sac. The arterial tunics were weakened at a given point, but not perforated. The aneurism in these cases approaches in character the pathological form, with this very important exception, viz. The artery above and below the tumor is not involved, and is usually found to be healthy. It is this important feature which renders this class distinct from both idiopathic and diffuse traumatic aneurisms so far as prognosis and treatment are concerned. Indeed, treatment of this form of aneurism by ligature of the artery on the proximal side of the sac is attended with excellent results.

In eight cases of axillary aneurism of this character cited by Mr. Erichsen, in which the subclavian was tied, not a single fatal result occurred. In all these cases the aneurism arose from stabs or gunshot wounds, and had existed for periods varying from two weeks to four years. I will add that no other author to whose works I have had access makes a study of this class of axillary aneurisms as distinct from those originating otherwise, and the brilliant results mentioned by Mr. Erichsen in the eight cases he records gave me much encouragement in the management of the case here reported. It is an important discriminative point in the surgical treatment of axillary aneurism which it is the object of this paper to emphasize.

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

OLEATE OF MANGANESE.—DR. FRANKLIN H. MARTIN, of Chicago, says, in the *Medical Record* of June 27, that since manganese first received notice in this country as a menstrual stimulant, and as a remedy in functional amenorrhœa, menorrhagia, and metrorrhagia, it has been a formidable problem to the minds of therapeutists and pharmacists to get it into an acceptable shape for administration. He has therefore had an oleate of manganese prepared, to be used as follows:

Of a twenty per cent. solution of the oleate, I should recommend that one drachm be applied to the abdomen of the patient, and its absorption promoted by friction produced by vigorous rubbing of the surface with the palm of the hand or with the fingers. The rubbing should be continued until the oil has entirely disappeared by absorption. In cases where it is found impracticable to apply it to the abdomen on account of tenderness, it may be applied to the spine or the inner surfaces of the thighs.

In cases of amenorrhœa it should be applied, if possible, every night for a week preceding the expected menstrual period, or at the time the menstruation is due and until it makes its appearance. In cases of menorrhagia or metrorrhagia it can be applied in smaller quantities every night until the desired effect is produced.

I am very anxious to see the profession give this preparation a good trial, because if there is any great value in this drug, it can only become popular as a remedy in some such unobjectionable form.

The oleate was prepared as follows: A solution of sulphate of manganese was made in distilled water, and to it a solution of sodium oleate was added. On mixing these two solutions gradually and with constant stirring, a precipitate of oleate of manganese resulted. This precipitate upon heating changed to a putty like mass. This was thoroughly washed several times with warm distilled water, to remove the sodium sulphate, and the resulting putty-like mass was the pure oleate of manganese. This oleate, when dissolved in oleic acid to the required per cent., is ready for use.

THALLIN.—PROF. MARAGLIANO, at a meeting of the Italian Medical Society, held in Genoa, April 28, 1885, reported the results of his experiments made upon thallin. He observed that in apyrexia thallin exercises a slightly depressing effect upon the temperature, and that the pulse and respiration are also slightly diminished in frequency, while the intra-arterial pressure is slightly increased.

In patients in whom pyrexia is present, thallin constantly lowers the temperature, the reduction varying with the dose. Doses of about four grains cause a reduction of about one and one fifth deg. F.; doses of seven and one-half grains a reduction of from one and four-fifths deg. F. to nearly six deg. F.; doses of eleven and one half grains reduced the temperature from two and one third deg. F. to seven and one fifth F.; while doses of fifteen and one half grains cause a reduction of from three and one half deg. F. to eight and one half deg. F.

The reduction of temperature ordinarily begins in an hour after the administration of the drug and attains its maximum in two hours if the diminution is about 2.7° F., and after three or four hours if it is greater. The effect of the drug persists from one to ten hours according to the dose. The reduction of temperature is ordinarily accompanied by perspiration, more or less profuse.

The disappearance of the fever is sometimes preceded by the shivering and chill. Frequency of the pulse and of respiration diminishes proportionately to the reduction of temperature and to the dose of the drug.

Thallin does not produce vomiting nor any other gastric disturbance, and may be administered in the quantity of 110 grains in twenty-four hours without inconvenience of any kind. It is found in the urine an hour and a half after its administration, and the greater quantity of it is eliminated in the first ten hours.

Twenty hours after the administration of the drug the urine does not give the characteristic reaction with the chloride of iron. After the administration of the drug, the urine assumes a characteristic darkish green color, which sometimes is absent after small doses. Prof. Maragliano has administered thallin in divers febrile diseases, and finds the fever depending upon pulmonary phthisis to be the least resisting, while that of fibrinous pulmonitis is the most intractable. Prof. Maragliano also finds that the drug diminishes the quantity of urea and of carbonic acid eliminated in twenty-four hours in apyretic subjects, and that it causes in the apyretic, as well as in patients with elevated temperature, a dilatation in the cutaneous vessels and an increase in the elimination of heat.—*Gazzetta degli Ospitali*, May 20, 1885. *Medical News*, June 27, 1885.

LEECH SECRETION IN BLOOD FOR TRANSFUSION.—DR. JOHN B. HAYCRAFT, in an article on coagulation of the blood (*Birmingham Medical Review*, May, 1885), states that he has prepared a watery extract of the secretion of the leech by cutting off the anterior third of a leech, placing it in absolute alcohol for the night, then cuts it into small pieces and extracts with a quarter of an ounce of 0.75 per cent. salt solution. Two drops of this added to a watch-glass full of blood will cause it to remain fluid, while another portion drawn from the same animal will clot in a few minutes. If an extract of three or four leeches be injected into the veins of a dog or rabbit, little constitutional disturbance will be produced, but if a small portion of blood be withdrawn from the animal, it will refuse to coagulate. In a few hours the blood is normal, the active principle of the secretion having been eliminated from the system by the kidneys. Some ten ounces of human blood shed into a vessel containing half an ounce of a 0.75 salt solution extract of three or four leeches would remain fluid for, at any rate, half an hour. It could be injected at leisure into the veins of the patient. It must be borne in mind that a pure watery extract may not be used, for the hæmoglobin would be dissolved out, and would produce dangerous symptoms when injected. In cases of threatened thrombosis this solution might be injected into a vein, and it would certainly prevent coagulation for a time.

NAPHTHOL OINTMENT FOR ITCH.—PROF. HARDY publishes the following formula in *l'Union Medicale*: Naphthol, 10 parts; vaseline, 100 parts. The powdered naphthol is to be dissolved in half its weight of ether. This solution is to be mixed with a portion of vaseline and heated to 30° or 40° C., until the ether has been entirely evaporated, when the rest of the vaseline is to be added, and the mass carefully triturated. The homogeneous ointment thus obtained is to be kept from the access of air. It may be applied at any stage of itch, whether it is complicated with other eruptions or not. The duration of the treatment varies from ten to fifteen days.—*The Medical Press*, May 20, 1885.

MEDICINE

TREATMENT OF BILIARY COLIC.—Among the other processes for which Kussmaul's procedure of washing out the stomach has been suggested, is biliary colic, due to impacted gall stones. At a recent meeting of the Berlin Medical Society, ROSENTHAL reported two cases treated in this manner. One was that of a woman æt. 33 years, who had been six months under his care with successive attacks of biliary colic, for which all the usual measures had been resorted to, morphine alone giving her relief. He then washed out the stomach, with a view to obtaining the sedative effect to which attention had already been called by Senator. As an apparent consequence the vomiting, which had been troublesome, ceased. She returned almost daily to have the operation repeated, and on the fourteenth day she brought with her two gall stones, each about as large as a hazelnut. Since then she has had no recurrence of the symptoms. The second case was that of a woman who suffered from very severe attacks of hepatic colic, with obstinate vomiting, and after washing out the stomach for a few days, not only did the vomiting cease, but the stones were also passed. Rosenthal did not attempt to explain the *rationale* of this treatment.—*Dublin Journ. Med. Science*, June, 1885.

HÆMORRHAGES INTO THE LARGER CAVITIES IN NEW BORN CHILDREN FROM A MEDICO-LEGAL POINT OF VIEW.—Hæmorrhage into the larger cavities of new born children has not been considered to any extent by writers on legal medicine. PROFESSOR STADFELDT, of Copenhagen, being called upon to make a report in a criminal case, undertook the examination of the reports of births and autopsies at the Maternity Hospital, of Copenhagen, during the past twenty years, during which time 25,000 births took place.

In this memoir, the author considers the hæmorrhages (ecchymoses) of the lungs and pericardium in the new-born. He notes that they are frequently produced at birth, and that, as they may continue for a considerable length of time, they should be looked upon with extreme caution as indications of suffocation after birth. Hæmorrhages of the cranial cavity may sometimes be considered in legal medicine as the result of suffocation at birth, but they are principally due to traumatism during labor. The child may live perfectly well with these losses of blood, particularly when they are circumscribed on the surface of the brain, and even with considerable hæmorrhage the child may be quite well some time after birth. He cites three cases of serious effusion of blood about the kidney and in the supra-renal capsule, *without* injury to the vertebræ and without a recognition of the cause of the hæmorrhage. Retroperitoneal effusion of blood was found extending all the way from the diaphragm to the pelvis. This occurred in three cases of presentation of the pelvic extremities, with extraction by the feet, and very difficult delivery. The hæmorrhages were probably produced during delivery, either by too great tension of the lumbar tissue, by direct pressure with the thumbs, or by raising the body too far while disengaging the arms.—*Nordiskt Medicinskt Arkiv*, Bd. xvii, Hft. 1.

SURGERY

RARE FORMS OF KELOID DISEASE.—MR. JONATHAN HUTCHINSON contributes an article on this subject to the *Medical Times and Gazette*, May 23, 1885, in which he details several interesting cases, with the following conclusions:

(1) That with keloid, as with other skin diseases, we must not expect too close a conformity to the type form.

(2) That for clinical convenience we may recognize several varieties of keloid, the prognosis as to spontaneous disappearance and proneness to return after excision differing much in each.

(3) That the first and most typical form is that in which keloid begins in very small perhaps forgotten scars, and slowly spreads far beyond their limits into sound skin. In most cases the extension and duration are indefinite, and the hardness, glossiness, abruptness of outline, etc., are always well marked. The proneness to recur very quickly after excision is very great in these.

(4) That in the second group, in which keloid growth begins in the middle of large scars, such as those of burns, it is seldom so well characterized. It often does not extend beyond the scar, and often, especially in young persons, soon begins to soften again and to gradually disappear.

(5) That in a third form the keloid growth is deeper, and never produces the glossy, superficial, elevated and spurred patches which occur in the others. These cases are very slow, and show but little tendency to spontaneous disappearance. They do not develop in connection with large scars, but rather with inflammatory damage to the skin. They are less prone than the others to recur after excision.

(6) That although definite scars almost invariably precede the formation of keloid, yet that there are allied conditions which result rather from inflammation after injury than from anything which is demonstrable as cicatrix.

(7) That the cases of multiple keloid prove either that there is in some persons a remarkable tendency to the disease, or that primary patches have the power of infecting the blood and producing others.

(8) That there is little or no clinical proof of tendency on the part of keloid to pass into cancer.

REMOVAL OF A CALCULUS FROM THE VERMIFORM APPENDIX FOR THE RELIEF OF RECURRENT TYPHLITIS.—The English medical journals give us an interesting report made by MR. CHARTERS J. SYMONDS to the Clinical Society of London on May 8, 1885, of an operation which was suggested by Dr. Mahomed. The case was that of a man aged 23, who had typhoid fever a year ago. In January, 1883, he was seized during the night with pain in the right iliac region; this increased in severity, and at the end of a week he was unconscious, remaining in this state four days. The illness lasted seven weeks. During the first week he vomited everything, and his bowels were not opened for ten days. During the whole time there was great tenderness in the right iliac fossa. Soon after this, on getting about, he noticed a hard lump in the right groin, about the size of a walnut; sometimes this swelling was painless, at other times it was very tender. Since this illness he has had repeated attacks of pain in the right iliac fossa, which come on suddenly and last one or two days. The pain is relieved by poultices. At first these attacks recurred about once a month, but during the last five weeks he has had six attacks, and they have been increasing in severity. July 13 he was seized while at work with severe pain in the right iliac region, which "doubled him up." He felt sick, but did not vomit, and was obliged to leave his work. He applied poultices, with turpentine, and obtained some relief, and remained in bed till his admission to Guy's Hospital, July 16. On admission, there was to be felt in the right groin, on deep palpation, a small, hard lump, about ¾ inch by 2 inches, running parallel with Poupart's ligament. This history repeats itself until August 24, when, as everything seemed quiescent, it was decided to explore the right iliac fossa. The lump was oval in form, well defined, and only slightly tender.

It was therefore decided to cut down upon the lump to remove a calculus present, or drain a cavity, should pus be found. Chloroform was administered, and, under the carbolic spray, an incision was made as for ligature of the external iliac, and so arranged that its centre corresponded with the position of the lump. The structures in front were divided and raised out of the iliac fossa, when the lump could be plainly felt from behind, and as yet the peritoneal cavity had not been opened. A vertical incision was now made over the hard lump, and a small calculus exposed. The opening was then enlarged, and the calculus removed. The soft and purple mucous membrane of the appendix was seen and its tortuous course from the aperture could be traced upward towards the cæcum, so that there seemed no doubt of the canal having been opened. There was no channel to the cæcum, and no pus or other fluid around the calculus, nor any fæcal or unpleasant odor. The peritoneum was not opened, so far as could be determined. The calculus was oval in shape, smooth on the surface, and measured ¾ inch long and rather more than ½ inch wide. On section, it showed a laminated calcareous capsule, enclosing hardened fæcal matter.

Antiseptic dressings were used, and in fourteen days he was discharged at his own request. A month later he was again admitted, suffering from a sinus three inches long, discharging a thin yellowish fluid, and the hard swelling noticed when he was discharged. A little over two weeks later he was discharged, the sinus having closed and the man being in good health, which continued up to the time of being last heard from, eighteen months later.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, JULY 11, 1885.

THE ORGANIZATION OF THE INTERNATIONAL MEDICAL CONGRESS OF 1887—AND THE RECENT MEETING OF THE GENERAL COMMITTEE OF ARRANGEMENTS IN CHICAGO.

If things done in haste are liable to be repented of at leisure, we are inclined to think this liability will apply with much force to the recent acts and expressions of certain members of the profession in Philadelphia, and perhaps in one or two other cities, concerning the measures for the organization of the Ninth International Medical Congress. Our readers will find an account of the acts to which we allude in the letter of our Philadelphia correspondent in this issue of the JOURNAL, which we publish for the purpose of giving their own version of the matter, and not because we approve of either the proceedings described or of the tenor of the letter itself. A more formal and official report of the doings of the twenty-eight members of the profession in Philadelphia, aided by one from Louisville, Kentucky, can be seen in the columns of the *Medical News*, of Philadelphia, for July 4, 1885. That our friends in the Quaker City have moved with undue haste, will appear from the fact that the Committee of Arrangements in session in Chicago did not adjourn until the afternoon of the 25th of June, and the meeting alluded to in Philadelphia was held on the evening of the 29th, before there had been time for the Secretary of the Committee on Organization to prepare the revised rules and appointments for the press, and consequently before they could possibly have anything more than a partial verbal report from some members of the Committee, on which to base their action. But notwithstanding this they proceeded with all due gravity to adopt *unanimously* the following preamble and resolution:

"WHEREAS, Certain serious changes have been recently effected in the preliminary organization and rules for the International Medical Congress of 1887, it has seemed desirable for the members of the General Committee and of the officers of the Sections resident in Philadelphia to meet for consultation; and

"WHEREAS, It has appeared that these changes are inconsistent with the original plan, and detrimental to the interests of the medical profession in America, and of the International Medical Congress, therefore be it

"*Resolved*, That we, the undersigned, consider that our duty to the profession and to ourselves requires us to decline to hold any office whatsoever in connection with the said Congress as now proposed to be organized."

That the reasons given in the preamble for the course of action announced in the resolution are disingenuous, to say the least, and entirely deceptive, we shall show more fully when we have for publication the full copy of the revised rules and plan of organization as adopted by the committee during its recent session in this city. It will then be shown that the only change in the proposed "preliminary organization" of the Congress was the dropping of *one* vice President and the adding of four or five others. The only changes in the Sectional organizations were the reducing of the number to sixteen by merging three with others, and the changing of four of the chairmen, leaving twelve unchanged, and not a single rule relating to the working or modes of action of either of the general sessions or of the Sections was materially changed. Where, then, are the alleged changes so "inconsistent with the original plan" as to be "detrimental to the interests of the medical profession in America"?

Do they consist in the simple fact that the present Committee on Organization, instead of ostentatiously making its own committee officers *the officers of the Congress*, simply adopted the ordinary organization of a Committee of Arrangements to make suitable preparations *for a Congress?* Or, after all, are we to look for the real reasons prompting the resolution to the fact stated by the editor of the *News*, when he says "the management of the matter (the preparation of the Congress) has passed into the hands of a very different set of men from those who had charge of it at the outset?" Or, as still more pointedly indicated in the letter of our Philadelphia correspondent when he says: "There is no dissent to the determination in this city (Philadelphia) that what has taken place at New Orleans and at Chicago to the damage of the Congress shall not be sanctioned, even in appearance, or permitted to stand as the work of Philadelphia, at all, notwithstanding the fact that a Philadelphian is charged with having had a great deal to do with it." Is it possible that it is just the retention of this particular Philadelphian, as simply secretary of the Committee of Arrangements, that has so hastily moved the twenty-eight grave, learned and justly eminent members of the profession in Philadelphia to wash their hands of all further responsibility in regard to the International Congress? When the full proceedings of the Committee of Arrangements, during the session in Chicago, come to be published in a connected and correct form, and it is seen that such proceedings have made no essential change in the general plan of organization of the Congress, or in the rules adopted for its government, that of the four chairmen of sections previously appointed in Philadelphia three were retained in their places, and the fourth was disturbed only by transferring him to the vice presidency of the section with which his own section had been united, and instead of confining the membership of the Congress to the membership of the American Medical Association, as is alleged, nearly or quite one half of the sixteen chairmen of sections re-appointed are not members of that organization, the medical world will not fail to see that the only foundation for the hasty movement of our honored confreres in Philadelphia *is* the simple change in the personel of the Committee of Arrangements and the practical denial of the assumption that the "various eminent specialists" of three or four cities and the medical profession of the United States are synonymous.

And if those who have been in such haste to condemn the action of the National Association and the present Committee of Arrangements for the Congress, do not wish to occupy the unenviable position before the world of men determined to rule or ruin, they will take much more time to think before they make their next move.

NUTRITIVE DRESSING OF LARGE GRANULATING SURFACES.

In the *Therapeutic Gazette*, May, 1885, DR. WM. BARTON HOPKINS, of Philadelphia, calls attention to a method of dressing large granulating surfaces which seems to offer considerable advantages in two ways: as a method of giving food to patients who, for obvious reasons, cannot take sufficient nutriment into the stomach, and as a very suitable method of dressing granulating surfaces. As illustrative of this method of "Nutritive dressing," Dr. Hopkins reports the case of a man, 36 years of age, who, while coupling cars, had his right elbow caught between the buffers, which nipped the limb, squeezing the forearm and elbow through a long tear in the integument.

There was no bone or joint injury, and no tissue was lost, but the greater part of the integument of the forearm and elbow had been stripped off, and lay curled up on the anterior aspect of the limb. "After being carefully washed with carbolated water, the wound, which extended from the lower part of the forearm to a point about four inches above the elbow, was loosely approximated, and dressed with carbolized gauze, dusted with iodoform. Two days later, owing to the high grade of inflammation which followed, this dressing was discontinued, and irrigation with carbolated water (one part to forty) used instead, and aconite was given internally. General sloughing of the entire flap of integument, and also of the muscles of the arm and forearm, followed. The elbow joint narrowly escaped involvement, its whole contour becoming plainly visible, covered only by capsular ligament, which latter, however, fortunately remained intact. Owing to the perfect drainage which could be obtained, and free irrigation, which was persistently continued for two weeks, the great mass of sloughing, gangrenous tissue remained entirely free from odor, and, notwithstanding the patient grew exceedingly weak and became rapidly emaciated, his temperature seldom exceeded 100°, and he showed no symptoms of sepsis. At the end of three weeks the sloughs had mostly come away, and healthy granulations began to fill up the depressions and even off the surface of the large ulcer remaining. Five weeks after the accident improvement had come to a standstill. The excessive drain from a suppurating surface, which at this time extended over an area of one hundred and five square inches, began to tax too severely his already enfeebled nutritive powers. He had complete anorexia, became nervous and irritable, had night-sweats, and his temperature became elevated, reaching 102° and 102½°. He had beginning hectic. Cicatrization had been going on for some time, but was feeble and tardy, while the discharge from the ulcer was free and comparatively healthy."

Dr. Hopkins then assumed that a granulating surface, of sufficient size, might be used as a medium by which to administer nutritive material, "and that certain such materials could be applied to it which would not interfere with the processes of cicatrization." For this purpose he used an emulsion of cod-liver oil, to an ounce of which five grains each of pepsin and pancreatic were added. The granulating surface was therefore dressed once a day with lint soaked in this preparation, and with the very best effects. The general and local conditions improved very soon, and Dr. Hopkins thinks that the improvement can be fairly attributed to the change in the dressing, since no change was made in the general treatment while the experiment was in progress. The appetite improved rapidly, "food was taken in much larger quantities, was eaten with relish, and was properly digested."

"The effects upon the ulcer were clearly secondary to those upon the general condition, as no changes were noticed in it until after marked improvement in the latter had occurred. Then it began to cicatrize with rather remarkable rapidity, in fourteen days having become reduced in area to seventy-seven square inches. The patient's face had lost its sunken, drawn expression, and he was now able for the first time to be out of bed. A number of skin grafts were applied at this time, and the dressing therefore discontinued, lest it should interfere with the process. Ten days later, several of the grafts having been found to have taken, the nutritive dressing was reapplied, and continued for two weeks longer. The indications for its use, however, seemed to have ceased, and no particular effect was noticed, except that healing progressed favorably with it, and that it was otherwise unobjectionable. The ulcer was afterwards strapped until the patient was transferred to the out-department, about four months after the accident. Three small ulcers remained, the dimensions of which were, respectively, about two by two and one half inches, one by one and one half, and one by one. Owing to loss of structure and cicatricial contraction, there was little movement at the elbow, but the hand was quite useful."

With Dr. Hopkins we would recommend that surgeons take every opportunity to test this plan, which certainly seems an admirable one in cases of exhaustion after extensive loss of superficial tissue from wounds, burns, scalds or whatever cause. It is his opinion that it would be most frequently applicable after burns, as the mortality after such injuries is very often due to the inability of the digestive system to furnish nutritive matter sufficient to compensate for the waste attendant on prolonged excessive suppuration.

THE SANITARY ASPECTS OF THE FOURTH OF JULY.

During the past ten years more than ten thousand people have had reason to regret the manner in which the fourth of July is usually celebrated in America. We might say that more than ten thousand have regretted it, but it is best to be on the safe side, and certainly ten thousand cases are sufficient upon which to base definite conclusions. We do not refer to the patriotic and uninjured citizen who regrets having spent too much money in exuberant rejoicing, doubtless there are many of this class. But we cannot think that the present mode of celebrating the day is looked upon with entire favor by those who have received injuries of various kinds from the many noise-producing agents which are inseparably connected with a celebration in the infantile American mind. These injuries are of two classes. First, direct bodily injuries, such as are produced by the explosion of gunpowder, fireworks, and that inoffensive-appearing though tetanus-provoking toy pistol, and secondly, indirect injuries to extremely nervous and sick people, produced by the noises emanating from the various instruments which delight the hearts of the little ones. It may be said also that various injuries are caused both directly and indirectly by an agent, in no little demand among adults for purposes of celebration, which, while quite noiseless in itself, creates an appetite for noises in those who use it too freely.

The various injuries reported on July 5 and 6 as having arisen from accidents on the fourth, due directly and indirectly to exuberant patriotism, footed up no less than two hundred and nine, not including fires, and it is quite probable that there were many not reported by the papers. It is true that but a small portion of the injuries were serious, but it is not the less true that they were avoidable. Some of them, however, were of a very serious nature. Such things as rockets, for example, are capable of causing injuries of a very serious or fatal nature. Here in Chicago, during the celebration of the fourth, one person received a fracture of the malar bone, and extensive injury to the face from a rocket, and another was severely wounded on the head. A year ago a woman was killed by a rocket penetrating the eye, and two years ago a man was killed by one. Numerous cases of tetanus have been caused by injuries from toy pistols, severe and fatal injuries have been caused by the premature firing of toy and other cannon. Injuries have also been received from fire-crackers and other varieties of fire-works. Besides the dangers to health, limb and life, the injuries that have been caused to property within, say, the past ten years are almost countless, houses have been burned, horses attached to vehicles have been frightened and have destroyed the vehicles, and in many cases have injured the occupants.

We have already referred to the fact that the noise attendant upon such demonstrations very seriously affects the welfare of sick persons When a person is in the delirium of typhoid fever, for example, the explosion of a large firecracker may make all the difference of life or death, and the same may be true in other cases One does not need a medical education to know that noise is a very important factor in disease or illness, for everyone knows how often perfect quiet is enjoined upon the members of a family in which there is a case of illness Everyone knows that the rattling of a heavy vehicle over the stones of a street will sometimes seriously compromise the condition of an ill person, but this is by no means so serious as the sudden shock produced by an explosion It is entirely possible that a person suffering from severe heart lesion might be killed by such a sudden shock

In view of these facts, is it not right that authorities should prohibit noisy demonstrations within the limits of a city? If such demonstrations were capable of conferring any good whatever upon the community at large, there might be some question as to the expediency of such prohibition But they confer no good So long as public sentiment is in favor of having certain legal holidays, it is perfectly proper that there should be such, and when the observance of such days is kept within reasonable bounds there can be no objection to them But demonstrations which are of no positive good to any, and which entail a positive injury on some, should be absolutely prohibited They have been prohibited for more than a year in New York city, and to some extent also in Philadelphia It is not simply a question of expediency, it is a question directly connected with the public health, and health officers should direct the attention of the proper authorities to it It is not only the privilege of the health authorities to call attention to these matters, but as protectors and preservers of the health of the people it is their duty, and it is equally the duty of the police authorities to prohibit whatever may injure health, limb, life or property It it scarcely necessary to say that these remarks concerning the midsummer national holiday are equally applicable to other days celebrated on "the American plan"

THE OWNERSHIP OF A PRESCRIPTION

The following paragraph has appeared in one journal or another for several weeks

"The Supreme Courts of New York and Massachusetts have settled the matter as to who owns a medical prescription The substance of the decisions is, that the physician, in prescribing, gives the patient a written order for drugs, and their delivery terminates the operation The druggist may, on his own responsibility, renew the drugs, for he is a merchant, and has a right to sell drugs in any shape He is not bound to give a copy of the prescription, nor even to keep it"

In the first place, it would be of interest to know how this decision settles the matter of ownership There is nothing in it to indicate whether the physician, druggist or patient, or all three own it If the delivery of the drugs on the written order of the physician *terminates* the transaction, how is it possible that the druggist may renew the prescription save on a written order for renewal? If he has that right, the question of ownership lies between the druggist and the patient, and the transaction has not terminated, but remains in force so long as the druggist and patient live If a druggist may, on his own responsibility, renew one prescription, he may renew any, he may renew an order for a pint of sherry three times a day, or for five one-grain doses of opium as often as the patient calls for it

The statement that the druggist is a merchant and "has a right to sell drugs in any shape" is true only under certain conditions, there are certain drugs the sale of which, save on a physician's prescription, is illegal The law gives the physician the sole right to say whether the druggist may sell these drugs in any case, and hence the presumption of ownership in prescriptions calling for these drugs is certainly in favor of the physician And there is no reason whatever for holding that the law should make a distinction, as to ownership, between one prescription and another—nor for holding that it is illegal for the druggist to sell certain poisons, in the first instance, except on the written order, while he may *renew* them as often as called for without a second written order For, if the physician alone has the right—the legal right—to say whether a certain person may or may not take certain medicines in the first instance, he has the same right to say whether he may continue to take them after the amount first ordered has been taken, and it is a manifest absurdity to hold that, because certain drugs are ordered at one time they would certainly, or even probably, be ordered one month afterwards And there seems to be good reason for holding that a druggist who renews a prescription calling for the authority of a physician, save on those drugs which can be sold only on prescription, is indictable under the Poisons Act (some form of which is in force in almost every State), The necessary inference, therefore, is that the Courts have drawn no conclusions from false premises, and have left us as much in the dark as before

SOCIETY PROCEEDINGS.

CHICAGO GYNÆCOLOGICAL SOCIETY.

Stated Meeting Friday, May 29, 1885.

THE PRESIDENT, H. P. MERRIMAN, M. D.,
IN THE CHAIR.

An inaugural thesis, entitled

THE NORMAL POSITION OF THE UTERUS AND ITS RELATION TO THE OTHER PELVIC ORGANS,

was presented by FRANKLIN H. MARTIN, M. D., (Chicago Medical College, 1880,) and read by the Secretary, Dr. Edward Warren Sawyer.

The extreme theories of Schultze, Fritsch and Savage were opposed for the following reasons:

1. In extreme anteversion, the wave impulse would strike the posterior broad surface of the body of the uterus, and drive it down upon the bladder and anterior wall of the vagina, while, on the other hand (the perpendicular theory of Savage), the anterior broad surface of the body would receive the impulse to an equal disadvantage, displacing the uterus backward and driving the cervix downward, while if the uterus occupied the position between these two extremes, the narrow crest of the fundus would receive the impulse in the line of the axis of the uterus and all the force would become equally distributed through all of its supports. Here, too, the organ would not so directly receive the whole impulse, as it would be equally dispersed upon its sides and the posterior ligaments and anterior supports, and its lateral attachments would receive, to an equal extent, their portion of the impulse.

2. The manner in which the bladder collapses, to our mind, precludes the possibility, or at least the probability, of the uterus occupying normally the position of extreme anteversion. The bladder, when collapsed, or when empty, is a triangular shaped body, not flat like a plate. The base corresponding to its peritoneal surface, the apex corresponding to the urethra. The posterior or inferior surface corresponds to the anterior wall of the vagina, to which it is intimately attached, the anterior wall corresponds to the symphysis, to which it is loosely attached. It is readily seen, then, that the bladder distends only in the direction of the peritoneum, or its one free surface. According to the extreme anteversion theorists, the free surface of the bladder and the uterus are in apposition. If such be the case, the uterus changes its position constantly, as the bladder normally relaxes and contracts,—this seems to us very improbable. We believe that this space is usually filled with the light coils of the small intestines.

3. The broad ligaments receive their external attachments at a point about equidistant from the centre of the sacrum posteriorily, and the pubic junction anteriorly, in such a way as to divide the plane of the brim of the true pelvis into about equal halves. If the body of the uterus occupies a position in the centre of the pelvis on a direct line with the ordinary attachments of these ligaments, which it is at least rational to believe is the case, it occupies a position between the perpendicular of Savage and the extreme anteversion of Fritsch.

4. With extreme anteversion, the cervix, with the fundus occupying a position behind the symphysis would necessarily have to occupy a position far back in the pelvis, within three fourths of an inch of the sacrum—with a normal confirmation of the parts, this is impossible without interfering with the rectum.

5. If we take the measurements of Foster and Litzmann into consideration, we can at once demonstrate the impracticability of the position given by Savage,—*i. e.*, the perpendicular. The cervix occupies a position normally at a distance of one and one-half inches from the sacrum, the rectum intervening. It is impossible for the uterus to assume anything like a perpendicular with the cervix in this position, on account of the anterior curve of the sacrum above, which necessitates an anterior version from the perpendicular of at least fifteen degrees.

PROFESSOR W. W. JAGGARD was pleased with the selection of the topic, and its mode of treatment, but did not agree with Dr. Martin in all his conclusions. Bandl had made a correct statement of the diversity of opinion on this subject, in his essay on "The Normal Position and the Normal Relationship of the Uterus, and the Pathologico Anatomical Causes of the Symptom of Anteflexion" *(Archiv für Gynäkologie, Band XXVI, Heft 3, 1884)*, read before the Gynæcological Section of the Versammlung deutscher Naturforscher und Ærtze in Frieburg, September, 1883. "In the course of time, almost every position of the uterus, with the exception of prolapse, has been accepted as the normal by different anatomists and gynæcologists, and particularly by the more eminent ones."

Kolliker (1882), from a series of examinations of the cadavers of girls, from ten to eighteen years old, has concluded that the uterus is not bent, nor curved upon itself, but is straight, and that its long axis corresponds with the principal axis of the small pelvis. Its position is variable within certain limits, depending upon the condition of the bladder and rectum. This opinion coincides closely with judgments of Kohlrausch (1854), Le Gendre, (1868), Freund, Carl Braun, (1857), J. Marion Sims, (1855), Langer, (1881). Professor Paul F. Mundé, in his recent excellent work on "Minor Surgical Gynecology," favors these views to the extent that he says, "with the woman in the recumbent position, the examining finger is unable to touch the body of the uterus before or behind the cervix, if the uterus is normally situated." Bandl, in the paper, to which allusion was made, confirms Kolliker's view. The evidence he furnishes is of a high order. His methods of investigation were: 1. The attentive examination of living women. 2. Examination and observation before and during the operation of laparotomy. 3. The bimanual examination of the organ in cadavers, before and after abdominal section. 4. The comparative anatomical examination of many uteri.

DR. PHILIP ADOLPHUS thought, with Emmet, that "there is no common standard by which to determine the proper position for the uterus in all women, but that in each individual there is a point, or plane, in the pelvis which the uterus should occupy when she is in a state of health and not pregnant." He referred in detail to Emmet's "normal or health line," and to the pathological character of displacements above or below this line. It was a matter of relative insignificance whether or no the long axis of the uterus coincided with any particular pelvic axis. In the concrete case, the sensations of the individual would indicate a normal or abnormal position.

PROFESSOR DANIEL T NELSON said the uterus was fixed in a position of unstable equilibrium by the annular and other ligaments. It could move to a certain degree in every direction, and return to its original, normal position. Displacement above or below Emmet's "health line" was productive of symptoms, if the uterus remained fixed in such a position, as was usually the case when violence caused the dislocation. Departure from the principal axis of the pelvis was a comparatively insignificant moment, viewed absolutely. The vagina and perineum are not primary supports of the uterus, and only assume this function, when, as the result of the relaxation of the proper uterine supports, the organ is displaced downwards. This secondary character of the vaginal and perineal support was capable of demonstration by the examination of a woman in the erect attitude. Upon coughing or sneezing the uterus would descend and receive support from vagina and perineum, only to regain its original position when the excitant was removed. This remark applied exclusively to normal organs in normal position. He wished to emphasize the statement that the rectum was not the normal receptacle for the faeces. Anatomy and physiology teach that in the normal condition the gut is empty up to the sigmoid flexure. The sigmoid flexure is a sort of valve to retain fæces.

He gave the history of a case of retention of urine in a puerperal woman, in which the bladder was displaced towards the right. He would like to ask the Fellows if this displacement, observed in a single case, corresponded with their observations.

PROFESSOR CHARLES WARRINGTON EARLE related the history of a case of retention of urine in a puerperal woman, the bladder displacing the uterus upwards and backwards. Upon the introduction of a catheter, four quarts of urine were evacuated and pelvic viscera returned to their normal relations.

DR EDWARD WARREN SAWYER said the uterus had great latitude of movement antero posteriorly and laterally, elevation above or depression below the normal plane, even to a slight degree, was productive of pain. The introduction of a pessary, which merely elevated the uterus when partially prolapsed, without altering flexion, was sufficient in many cases to afford complete relief.

While a student in the Medical Department of Harvard University, he had taken plaster casts of the vagina. Such casts were of uniform shape, while they differed in size. They were curved, convex posteriorly, concave anteriorly. They were never shaped like an S. The curve did not correspond to that of the anterior surface of the sacrum, but to the floor of the pelvis.

DR H T BYFORD thought Dr Sawyer's experiments were faulty. When plaster of Paris was injected into the vagina, with the rectum empty, the vagina would act exactly as the rectum would under similar conditions.

THE PRESIDENT complimented the author of the paper on the careful, judicial mode of treatment of his difficult subject. He agreed with Dr Adolphus, Dr Nelson, Dr Sawyer, that elevation above or depression below a certain horizontal plane was of greater importance, in the production of symptoms, than deviation from the principal pelvic axis antero posteriorly or laterally.

The normal position of the uterus was as variable as the quantity of blood lost at a menstruation. Every woman was a law unto herself. He referred in detail to Robert Barnes's theory of uterine support, and concluded by recommending Bozeman's plan of columning the vagina, when a hard rubber pessary could not be borne.

Professor Christian Fenger, M D (Copenhagen, 1867), and Franklin H Martin, M D (Chicago Medical College, 1880), were then elected Fellows of the Society.

KENTUCKY STATE MEDICAL SOCIETY

(Continued from page 24.)

THURSDAY, JUNE 25—SECOND DAY

AFTERNOON SESSION

DR DUDLEY S REYNOLDS read a

REPORT ON OPHTHALMOLOGY

The paper dealt more particularly with the errors and sources of error in operations for strabismus. The reader discussed the necessities for knowing the cause of the squint, and reviewed the opinions of different authors on this subject, he has long been impressed with the difficulty of correcting this trouble. It is important to correct it as soon as possible. In his opinion the patient should not be secluded from the light after operation, but should be treated with mild mydriatics. All eyes tending to squint should be operated on immediately.

DR WILLIAM CHEATHAM, of Louisville, said that his rule was not to operate until the child was old enough to wear glasses, which usually is not before the seventh year.

DR E WILLIAMS, of Cincinnati, thought that we seldom get good results as regards binocular vision, and that there is something back of anomalies of refraction in squint.

DR WILLIAM CHEATHAM made a

REPORT ON OTOLOGY,

in which the principal subject of discussion was catarrh of the middle ear, earache. This, he thought, was a subject which could not be over written. Treatment has become more and more simple of late years. He reported a number of cases, and described his treatment by means of the fountain syringe. This was usually preceded by a purge of calomel and soda. He thought it very important that treatment should be begun early. He recommended leeches for local depletion, but the meatus should be plugged with cotton to prevent the leech from getting into the ear When fluid is present it should be evacuated Hot water is also valuable in the treatment, as is the dry treatment by zinc or boracic acid He uttered a warning against poultices, they should not be used until everything else has been tried

Dr J A Larrabee of Louisville, made the

REPORT ON DISEASES OF CHILDREN

The good of the nation demands the care of the children He considered fully the harm done in schools by over crowding and over-work, and also that done in factories and mills where children are made to do the work of adults In pediatrics we must learn the language of disease This, like other languages, must be learned while young Pediatrics must be commenced as a specialty He considered infant feeding, and dwelt upon its importance Cholera infantum, syphilis, scrofula, measles, scarlet fever, whooping cough and chicken pox were discussed He thought that high temperature often simulating peritonitis is due to some retained matter in the intestinal canal Purges and emetics, he thought, were giving place too much to chloral and the bromides for headaches In many of these cases a dose of castor oil was all that was necessary In every case of fever in children the tonsils should be examined, and the cause of the trouble will often be found there He had followed with much interest the study of micro-organism in the etiology of diphtheria He advocated the use of hypodermic injections of morphia and atropia in children, especially in cholera infantum In conclusion, he would advise more instruction and less medicine in childhood, good food, good sense, and an occasional dose of castor oil

Dr Webb, of Stamford, favored hypodermic injections of morphia in cholera infantum

Dr Howard, of Shelbyville, thought Dr Larrabee should differentiate between children in the country and those in the city

Dr Preston B Scott, of Louisville, thought as many children were overfed as underfed He looked upon morphia or opium in childhood as dangerous remedies

Dr E Williams wanted it understood that he was on the side of the children He was in favor of regular meals at regular times, and nothing in between times

Dr Wm Baily, of Louisville, in referring to the terms starvation and overfeeding, said there was no better way to starve than to overfeed In overfeeding we have impaired digestion He thought opium the remedy needed in anemia of the brain

Dr Pinckney Thompson, thought that impure air, bad food and mean drugs caused great mortality in the city When we have healthy mothers we have healthy children Healthy mother's milk is the best food Cow's milk is better than that of a sickly high strung woman You can't get good milk in the city unless you get it from a country cousin He has given morphia 1-30—1-20 grain, atropia 1-200 grain in children six years of age Has given ⅛ grain morphia and 1-100 grain atropia to child one year old for cholera infantum, and never had occasion to regret it

Dr Larrabee was surprised that the gentlemen did not understand the inverse susceptibility of children to atropia There is no dosage to the man who understands medicine, he gives only for its effect He thought it a golden era when the hypodermic syringe was introduced

Dr J Morrison Ray, of Louisville, read a paper on

WOUND OF THE ANTERIOR SEGMENT OF THE EYEBALL

Injuries of the cornea, iris and ciliary body are frequent, for this reason they demand the consideration of the general practitioner The promptness of action required in many cases causes them to be classed as surgical emergencies A history of the discovery of the preventive treatment of sympathetic inflammation was given It was maintained that the question most pertinent at the present time was not, would enucleation forestall sympathetic trouble This was thoroughly established But the question most pertinent is, How much injury can an eye sustain and still be retained with a minimum of danger to its fellow from sympathy?

Some, whose conservatism had given them bitter experience of sympathetic ophthalmia, may advise enucleation of an eye that by judicious treatment might eventually become useful A prominent British ophthalmologist was quoted as saying that he was satisfied that many eyes were sacrificed that by careful attention would have become satisfactory organs of vision Histories of cases of extensive injuries to the anterior hemisphere of the eye were given, the recoveries, under proper treatment, being most satisfactory In conclusion, it was urged that wise conservatism be practised in dealing with these cases The fact must never be forgotten, that if much inflammatory reaction followed, if the ciliary region is involved in a firm cicatrix, the iris and ciliary body to a state of chronic excitement, with an abiding tenderness in the region, the eye should be carefully watched and the patient warned of the dangers which menace the fellow-eye from sympathy The author agreed entirely with Swanzy, who says Never remove an injured eye "unless it contains a foreign body which could not be removed For inflammation may not come on, and thus the eye be saved"

EVENING SESSION

Dr J B Marvin, of Louisville, read a paper on

PRIMARY LATERAL SPINAL SCLEROSIS

This is a rare disease, and has only recently been recognized as a distinct affection, principally through the writings of Erb, 1875, Charcot, 1876, and Seguin, 1873 The disease is one of gradual onset, and of adult life The real cause is unknown It seems to attack robust, muscular persons, is attended with loss of power in the extremities, with muscular rigidity, spasmodic twitchings, tremors, and increase of the tendon reflexes The positive and negative symptoms show most clearly that the lesion is limited to the crossed pyramidal tract But few autopsies have been made

To Dreshfield and Morgan has been attributed the honor of first proving by dissection the connection of the symptoms of spasmodic paralysis with lateral sclerosis in a primary uncomplicated case of the disease

The diagnosis is often easy, though it may be extremely difficult It is especially liable to be confounded with transverse myelitis According to Charcot, the lesion in primary sclerosis is wedge-shaped, extends exteriorly to the pia mater, and interiorly as far as the posterior cornua This, he claims, distinguishes it from secondary lateral sclerosis The progress of the disease is probably the most chronic of all forms of spinal trouble Uncomplicated cases do not shorten life Prognosis is not favorable to recovery Authors have reported cases as having recovered, but when an anatomical lesion has occurred I cannot see how recovery is possible

Treatment Arsenic and the bromides, nitrate of silver, galvanism, water cure antiseptics, iodides, etc The reader closed with the report of an interesting case, and gave a number of microscopic and photographic views illustrated by the magic lantern

DR WILLIAM CHEATHAM read a paper on

NEURO-RETINITIS ALBUMINURICA

Having seen ten cases of this affection during his practice as an ophthalmic surgeon, he thought it well to report them After making the detailed report, he showed a number of microscopical and photographic specimens by the magic lantern He then spoke of the value of the ophthalmoscope in the diagnosis of renal disease, and showed diagrams of the normal and diseased fundus oculi In five of the cases reported, no renal trouble had been suspected by the family physician The connecting link between the trouble of the kidney and that of the retina has not been satisfactorily shown Some have ascribed it to urea others to albumen and cases are reported which support both these views The best prognosis can be made in those cases which follow the exanthematica, typhoid, and occur in the advanced stages of pregnancy No special treatment of the eye is indicated except rest and the avoidance of bright light

DR ORPHEUS EVARTS, of the Cincinnati Sanitarium, read a paper on

OVER WORK AS RELATED TO INSANITY

The alarming and much talked of increase of insanity in this country, is ascribed by common consent to the restless industry, enterprise and push of the American From 1870 to 1876, Dr Evarts had admitted 1204 men, supposed to be insane, to the hospital No distinction was made except as to chronicity and idiocy, which precluded admission Of the 1204 but 17 had received even a nominal academic education, and only 25 were properly professional men, 12 being lawyers, 9 physicians and 4 clergymen Of the remainder who lived by their wits, there were 1 actor, 1 author, 1 editor, 1 musician, 3 insurance agents and 1 gambler, making a total of 38 out of the 1,204 who might be said to live by brain work Of the 12 lawyers only 3 were of more than ordinary capability or reputation in the profession, and one of these had reached senility, the other two had been intemperate in the use of alcohol and tobacco Of those classified as physicians not one had been a student or thinker Inherited defects of organism, night riding and exposure, whiskey, opium, and tobacco excesses, poverty and ignorance, and neglect of personal hygiene would figure conspicuously in their clinical history Of the four preachers one was a "crank," one epileptic, and the other two were half starved and otherwise devitalized victims of the untoward circumstances of their birth

"Recollections of more than 4,000 insane persons that have come under my observation within ten years of continuous service as superintendent of a public hospital for the insane, aided by a review of the statistics, do not change the conclusions to be drawn from these selected examples nor do other observations, more fully and studiously made, of the inmates of a private asylum for the insane, extending over a period of six years, though a much larger proportion of such inmates are persons of more than the ordinary intelligence and acquirements of the general population of public hospitals for the insane The same general features of causation are seen through all disguises, viz an inherited potentiality, developed by a variety of mixed influences emanating chiefly from conditions of deprivation or excess I conclude, therefore, that while over-work, in the general acceptation of the term, is a prominent factor in the causation of diseases, some of which are manifested by mental disorders, over-work in the performance of mental functions is not a frequent or sole cause of such diseases"

(*To be concluded*)

Pyridine—Its Chemical History—Method of Administration—Soporific Effects—Its Value in Asthma

Pyridine is the name given to a new substance introduced by Prof Germain Sée in the treatment of asthma Wishing to ascertain the rationale of the treatment of asthma by the smoking of medicated cigarettes and the veritable physiological agent to which the cure is attributable, Prof See, in conjunction with Dr Bochefontaine, discovered by chemical analysis that the therapeutic action of the cigarettes was due to a uniform base formed by the combustion of certain plants and of certain alkaloids This substance is pyridine, which is developed during the distillation of dry organic matters in the products of bony tissues (animal oil of Dippel), coal tar, and certain important alkaloids, such as cinchonine, quinine and morphine, it is also found in the products condensed from the fumes of tobacco, and, finally, it is found in nicotine itself, in which a pyridic nucleus was discovered in 1880 by Cahours and Etard Whatever its origin or mode of preparation pyridine is a colorless liquid, which evaporates in the air at an ordinary temperature, giving out a strong penetrating odor It is mixible in water in all proportions, and forms with mineral acids very soluble salts, but which are easily disintegrated

The best mode of introducing pyridine into the organism is neither by subcutaneous injections of its salts, on account of their rapid disintegration, nor by the inhalation of pure pyridine, which provokes nervous troubles, it is by aspiration that it acts best. 4 or 5 grammes are poured on to a plate, which is placed in a closed room containing about 25 cubic metres of air. The patient, occupying a corner of the room, thus breathes the air mixed with the pyridic vapors, each sitting should last from twenty to thirty minutes, and be repeated three times a day. Absorption is immediate and the pyridine can be detected in the urine almost immediately after the commencement of an inhalation. The patients at once experience a marked diminution of the oppression so common to asthmatics, the breathing becomes easier, and they have no longer the intense longing for fresh air, results due to the fact that the sensibility of the pneumogastric nerve and the excitability of the medulla oblongata are considerably diminished.

The action of the heart during this time becomes normal. After each sitting, the patients feel an irresistible tendency to sleep, which becomes neither complete nor profound, and is not accompanied by insensibility. This effect of pyridine completely distinguishes it from the sleep produced by chloroform, ether, and the other anæsthetics in common use. While the sleep lasts, sensations, followed by reflex phenomena are provoked with difficulty, although contractile energy is maintained. The administration of pyridine is not followed by paralysis, convulsions, or tremors, but the muscles are relaxed, and temporarily lose their tonicity, in consequence of the lessened sensibility of the medulla oblongata and spinal cord. This modification of reflex sensibility is peculiar to pyridine, distinguishing it from the substances from which it is extracted, as, for example, nicotine and atropine.

The 14 cases in which Professor See tried the pyridine were 3 women and 11 men, with ages ranging from 30 to 68 years, 9 of whom were pure asthmatics, and 5 subjects of heart disease, they were all more or less relieved. One patient who had suffered from asthma from childhood, and another who had had the disease for 12 years were greatly relieved by the treatment with pyridine, but it had to be discontinued in consequence of troublesome attacks of vertigo and nausea. The patients who presented cardiac and renal complications declared that respiration became much easier by the inhalations. Professor Sée therefore concludes that pyridine is preferable to hypodermic injections of morphia, its action being less dangerous than that of the latter, and it does not affect the general health. Its use, however, is indicated only for the relief of the fits of asthma, but for the cure of the affection, Professor Sée places the greatest reliance on iodine and its preparations, for which he considers them as almost specific remedies, whether the asthma be of nervous or cardiac origin, while pyridine is the most useful adjuvant.

The following are the conclusions of the work addressed by Professor Sée to the Academy of Sciences on the treatment of asthma. 1. Whatever be the form of the asthma, whether it be primitive or of gouty or other origin, "ioduration" constitutes the veritable curative method. When iodism supervenes, pyridine should be employed, and it may be considered the most efficacious remedy against the attacks. In other words, pyridine is the best palliative, while iodine is the efficacious remedy. 2. Pyridine is superior to injections of morphia, its action is more durable and more inoffensive. 3. In simple nervo-pulmonary asthma the attacks may be completely arrested. For the severe form complicated with permanent pulmonary lesions, the treatment should be continued for eight or ten days after cessation of the attacks, in order to consolidate the amelioration obtained. In cases of cardiac asthma, with or without renal or dropsical complications, pyridine may still render the greatest service by combating the most persistent, the most distressing phenomena which torment cardiac patients, that is, oppression, whether continued or whether paroxysmal. The Feeling and Action of the Profession in Regard to the Proposed International Medical Congress, Wholesale Withdrawal from Participation in it—More Money for the University of Pennsylvania—The Women's Medical College, Facilities for Study, Arterio-Venous Aneurism—What the Women Write their Theses About.

The matter which at this time is most in the mind of the medical profession in this city is the prospect in regard to the proposed meeting of the International Medical Congress, in Washington, in 1887. It has been feared that the stirring up of sectional jealousy which took place in New Orleans, at the instigation of certain men who thought better of themselves than the committee on organization thought of them, might lead to action on the part of the enlarged committee which would make it impossible for a number of the original committee, and of their appointees, to retain their positions without a sacrifice of their self respect. This apprehension has been justified, it would appear, by the proceedings of the enlarged committee in Chicago, when such changes were made in the *personel* of the committee of organization and its appointees, and such a disposition was shown to put into prominent positions some of the men who are here thought to have been willing to risk the ruin of the whole plan for the Congress, in the hope that out of the troubled waters they might fish something to their own advantage, that there has been a feeling of strong indignation here, and the conviction has deepened that there is no hope of a successful or creditable meeting of the Congress while the management is in the hands of such men, and is subject to such influences, as were paramount at the meeting in Chicago.

As an evidence of this conviction, I may state of the symptoms of spasmodic paralysis with lateral sclerosis in a primary uncomplicated case of the disease.

The diagnosis is often easy, though it may be extremely difficult. It is especially liable to be confounded with transverse myelitis. According to Charcot, the lesion in primary sclerosis is wedge shaped, extends exteriorly to the pia mater, and interiorly as far as the posterior cornua. This, he claims, distinguishes it from secondary lateral sclerosis. The progress of the disease is probably the most chronic of all forms of spinal trouble. Uncomplicated cases do not shorten life. Prognosis is not favorable to recovery. Authors have reported cases as having recovered, but when an anatomical lesion has occurred I cannot see how recovery is possible.

Treatment. Arsenic and the bromides, nitrate of silver, galvanism, water cure, antiseptics, iodides, etc. The reader closed with the report of an interesting case, and gave a number of microscopic and photographic views illustrated by the magic lantern.

Dr. William Cheatham read a paper on

NEURO-RETINITIS ALBUMINURICA.

Having seen ten cases of this affection during his practice as an ophthalmic surgeon, he thought it well to report them. After making the detailed report, he showed a number of microscopical and photographic specimens by the magic lantern. He then spoke of the value of the ophthalmoscope in the diagnosis of renal disease, and showed diagrams of the normal and diseased fundus oculi. In five of the cases reported, no renal trouble had been suspected by the family physician. The connecting link between the trouble of the kidney and that of the retina has not been satisfactorily shown. Some have ascribed it to urea, others to albumen, and cases are reported which support both these views. The best prognosis can be made in those cases which follow the exanthematica, typhoid, and occur in the advanced stages of pregnancy. No special treatment of the eye is indicated except rest and the avoidance of bright light.

Dr. Orpheus Evarts, of the Cincinnati Sanitarium, read a paper on

OVER-WORK AS RELATED TO INSANITY.

The alarming and much talked of increase of insanity in this country, is ascribed by common consent to the restless industry, enterprise and push of the American. From 1870 to 1876, Dr. Evarts had admitted 1204 men, supposed to be insane, to the hospital. No distinction was made except as to chronicity and idiocy, which precluded admission. Of the 1204 but 17 had received even a nominal academic education, and only 25 were properly professional men, 12 being lawyers, 9 physicians and 4 clergymen. Of the remainder who lived by their wits, there were 1 actor, 1 author, 1 editor, 1 musician, 3 insurance agents and 1 gambler, making a total of 38 out of the 1,204 who might be said to live by brain work. Of the 12 lawyers only 3 were of more than ordinary capability or reputation in the profession, and one of these had reached senility, the other two had been intemperate in the use of alcohol and tobacco. Of those classified as physicians not one had been a student or thinker. Inherited defects of organism, night riding and exposure, whiskey, opium, and tobacco excesses, poverty and ignorance, and neglect of personal hygiene would figure conspicuously in their clinical history. Of the four preachers one was a "crank," one epileptic, and the other two were half starved and otherwise devitalized victims of the untoward circumstances of their birth.

"Recollections of more than 4,000 insane persons that have come under my observation within ten years of continuous service as superintendent of a public hospital for the insane, aided by a review of the statistics, do not change the conclusions to be drawn from these selected examples; nor do other observations, more fully and studiously made, of the inmates of a private asylum for the insane, extending over a period of six years, though a much larger proportion of such inmates are persons of more than the ordinary intelligence and acquirements of the general population of public hospitals for the insane. The same general features of causation are seen through all disguises, viz: an inherited potentiality, developed by a variety of mixed influences emanating chiefly from conditions of deprivation or excess. I conclude, therefore, that while over-work, in the general acceptation of the term, is a prominent factor in the causation of diseases, some of which are manifested by mental disorders, over-work in the performance of mental functions is not a frequent or sole cause of such diseases."

LETTER FROM PHILADELPHIA.

(FROM OUR OWN CORRESPONDENT.)

The Feeling and Action of the Profession in Regard to the Proposed International Medical Congress, Wholesale Withdrawal from Participation in it—More Money for the University of Pennsylvania—The Women's Medical College, Facilities for Study, Arterio-Venous Aneurism—What the Women Write their Theses About.

The matter which at this time is most in the mind of the medical profession in this city is the prospect in regard to the proposed meeting of the International Medical Congress, in Washington, in 1887. It has been feared that the stirring up of sectional jealousy which took place in New Orleans, at the instigation of certain men who thought better of themselves than the committee on organization thought of them, might lead to action on the part of the enlarged committee which would make it impossible for a number of the original committee, and of their appointees, to retain their positions without a sacrifice of their self respect. This apprehension has been justified, it would appear, by the proceedings of the enlarged committee in Chicago, when such changes were made in the *personel* of the committee of organization and its appointees, and such a disposition was shown to put into prominent positions some of the men who are here thought to have been willing to risk the ruin of the whole plan for the Congress, in the hope that out of the troubled waters they might fish something to their own advantage, that there has been a feeling of strong indignation here, and the conviction has deepened that there is no hope of a successful or creditable meeting of the Congress while the management is in the hands of such men, and is subject to such influences, as were paramount at the meeting in Chicago.

As an evidence of this conviction, I may state that, a few days ago a meeting was held of the members of the general committee and the officers of sections, resident in Philadelphia, at which it was unanimously resolved that the changes made at Chicago were inconsistent with the original plan for the meeting of the Congress and detrimental to the interests of the medical profession in America and of the proposed Congress, further, every one present declined to hold any office in connection with the proposed Congress as to be organized The full significance of this determination will be better understood when I say that there were present, or signed the resolutions after the meeting, among others, Drs Leidy, Stillé, Agnew, Bartholow, Wood, Parvin, Norris, Pepper, Weir Mitchell, Goodell, Gross Hays, Da Costa, Osler, and Yandell, of Louisville, who happened to be in the city, and was present by invitation This list, it will be seen, includes the names of some of the men in our profession most honored in this country and all over the world, some of them were among the founders of the American Medical Association, three were formerly Presidents of the Association, four are Chairmen of Sections of the proposed Congress, and one is the Secretary General just appointed at Chicago

I have information that the profession of Boston have just taken similar steps to express their dissatisfaction with the way things were managed by those who had control in Chicago, and that the profession in Baltimore will, in a day or two, do the same

It may be too late to save the Congress, but it is not too late to let your readers know what is the opinion here in regard to the men and methods which are held responsible for the disgrace which is likely to fall upon the whole American profession for its failure in this instance to justify the hopes and promises of those who invited the Congress to meet here in 1887 There is no dissent to the determination in this city that what has taken place at New Orleans and at Chicago, to the damage of the Congress, shall not be sanctioned even in appearance, or permitted to stand as the work of Philadelphia, at all, notwithstanding the fact that a Philadelphian is charged with having had a great deal to do with it This I write so that your readers may know, as they have a right to, what the sentiment here is in regard to this matter, and that they should have this information to guide them in placing the blame of the present unfortunate state of affairs where it justly belongs

The University of Pennsylvania has had another windfall Professor Tyndall, of London, has given a sum larger than ten thousand dollars to found a Fellowship in Physics This amount is the third of a sum acquired by Prof Tyndall from his lectures in this country in 1872, together with the interest which has accrued since then The recipients of the other thirds—for he has given the whole away—are Columbia College and Harvard University

In my last letter I gave some account of the College of Physicians of Philadelphia, and the facilities it affords for research to any student who may come properly recommended to it The progressive character of the college is perhaps in no way more strikingly exhibited than in the fact that its opportunities for study are embraced by a large number of women Among the grave male faces which are seen here poring over the books, are to be seen daily the faces of studying woman, with pen or pencil extracting what they can from the treasures of the library This fact is partly due to another, that we have in Philadelphia not only a Women's Medical College, but also the oldest medical college for women in the world, besides which, it is no exaggeration to say that it is the best in the world The Women's Medical College of Pennsylvania was organized a little over thirty years ago The first class graduated in 1857, and numbered eight women, the last class graduated this spring and numbered twenty-two The facilities for the study of medicine in this college are excellent, the faculty consisting of five men and five woman professors, or perhaps it would be better to put it, as it stands in the catalogue, five women and five men Besides these there are a number of instructors and lecturers, the entire list including some of the best known men in this part of the country In addition to the didactic instruction of the regular curriculum, the students have the advantage of a number of practical and laboratory courses, just as the students of the best colleges for men have There is also a flourishing Women's Hospital, so associated with the college as to constitute almost an integral part of it This hospital treated last year nearly five thousand patients, two hundred and sixty-two of whom were in patients Then there is a Nurse's Training School maintained in the hospital, which affords one of the best fields in America for instruction in this important department of treating the sick Already about a hundred nurses have completed the course of instruction and received the diploma of the institution

The Women's Medical College stands among those honorable institutions in this country which exact a three year's graded course of study from those who ask from them the degree of M D The winter session in this school is eight months long, too, instead of five, as is still too common elsewhere Even when the full course has been gone through, the examinations are conducted so severely as to weed out any who are not fitted to receive a degree At the last examination, four candidates were rejected out of twenty-six—a percentage which it would not be easy to duplicate in the colleges for men The class of students compares favorably with any other set of medical students Their teachers praise their diligence and assiduity, and seem to grow more convinced of the feasibility and advisability of the admission of women to the medical profession on the same footing as that of men the longer they are engaged in this work It is interesting to learn that the majority of the students of this college, expect to practice among women and children almost exclusively, yet the teaching in other departments is not neglected, nor their study slighted

Recently Dr W W Keen, Professor of Surgery, operated upon a very interesting case of arterio venous dilatation situated just above the elbow, in an otherwise healthy and blooming young Swedish woman, aged 18 years In addition to the local trouble, she presented the curious symptom of thrill and bruit above the clavicle. After other measures had been tried fruitlessly, Dr. Keen cut down upon the tumor and ligated the vessels involved, which proved a troublesome matter, since they were very numerous and bled profusely. The operation was done with the antiseptic precautions of Lister, in which Dr. Keen is a firm believer, and the patient thus far has done very well. After the operation there was no rise of temperature, and the subsequent treatment was of the simplest character.

In looking over the list of subjects of the graduating theses in the catalogue of the Women's Medical College, it is curious to observe that out of nearly 400 theses, only 44 are upon conditions physiological or pathological peculiar to women, and only 14 on such as are peculiar to children. Among the former, seven are on obstetrical subjects, four or five are on operations upon the vagina or uterus, three are on abortion, one on infanticide, one on fœticide, only one on dysmenorrhœa, one on the function of generation, one on amputations, and only two on women as physicians. Another curious matter in regard to the women who have entered the practice of medicine from this college is that, so far as can be learned from the list of the alumnæ, 64 out of the 398, that is, about 16 per cent., have married since their graduation. A large number of the graduates have settled in this city, and they seem to get along very well, notwithstanding the fact that as yet the County Medical Society has refused to elect any women to membership. The question of their admission arises from time to time, but as yet no one has received a vote sufficient to secure an election. In regard to this matter there is an honest difference of opinion between those who favor and those who are opposed to the admission of women to this society, and it is likely that each somewhat misunderstands the other. Time will doubtless make it all right. C. W. D.

INJURIOUS EFFECTS OF COCAINE.

Dear Sir:—Having seen recently, in the different medical journals, numerous statements of the unpleasant effects of the continued use of cocaine in eyes, subsequent to operations, producing turbidity of the cornea, I have thought that a brief statement of my own experience with its effects during the last six months, not only upon my patients, but upon myself, might be of interest, as I think it accounts for this unpleasant effect of the drug.

The anæsthetic influence of cocaine, especially upon mucous membrane, is conceded, but in addition to its anæsthetic influence, it has a remarkable influence upon the vaso motor nerves, exciting contraction of the organic muscular fibres of the arterioles. This influence is also known, but I think it is overlooked in many of these cases that are reported unpleasantly. This vaso motor influence is especially noticeable, when cocaine is applied to hyperæmic, or old chronic inflammatory membranes. Within a few minutes after its application to such eyes, there is a remarkable depletion of the vessels, and the membrane, which before the application was engorged with blood and lymph deposits, is now pale and comparatively blanched, and in some cases remains so for almost two hours. Now I can readily see, that in operations upon an eye in which the membrane itself is in its normal state and the vessels scarcely perceptible to the naked eye, that this driving of the blood from the vessels, would most likely be overlooked, and by continuous applications of cocaine to allay any pain subsequent to an operation, there could be such absolute depletion—the sensory nerves being paralyzed, and the vaso motor under an irritant or stimulant influence—that turbidity, and finally necrosis of the cornea might ensue by thus depriving the parts of the necessary blood to maintain nutrition of the delicate membrane.

Atropine, instilled into the eye, reverses this state of affairs, especially motility. The irritability of the vaso motor nerves is overcome, reaction is established, arterial tension increased, and the ill effects of the continued influence of cocaine are soon righted, turbidity of the cornea clears up and the structure assumes its normal state. Such I conceive, from my own experience with the drug, is the cause of the unpleasant effects recently reported.

I think the anæsthetic influence of cocaine can be maintained for an indefinite period by repeated applications, if, at the same time, a sufficient quantity of atropine be instilled into the eye to overcome the irritant influence of the cocaine upon the vaso motor nerves, thereby maintaining a sufficient blood supply to overcome any malnutrition of the cornea. I would be pleased to hear from others on this subject.

Respectfully, J. CRAFT, M.D.

Cleveland, Ohio.

PROPHYLAXIS OF DIPHTHERIA.

Dear Sir: I have read with much interest Dr. Nunn's paper, and the discussion had thereon, published in your issue of June 13, and take pleasure in adding my testimony to the value of biniodide of mercury in the treatment of severe cases of diphtheria. While pleased, however, with the admirably written paper, I was disappointed at finding no reference to the prophylaxis of the disease. Is it not as much the duty of the physician to prevent disease, or check its spreading, as it is to cure existing cases? In the *Therapeutic Gazette*, some seven years ago, I published my theory of the prophylaxis of diphtheria, and the article was largely copied by medical journals in this country and Canada. Having then had only a few opportunities for testing the trustworthiness of the theory, I requested practitioners who might test it, to send the results to me, and I have since that time received scores of letters from physicians, embracing territory from Maine in the East to California in the West, and the letters, with very few exceptions, corroborate my experience, which has been, that in no instance where the prophylactic remedies were faithfully administered did they fail to restrict the disease to the person first affected by it.

The cases, during the past seven years, in which I have tested the trustworthiness of the prevention, have embraced all the degrees of virulence from the exceedingly mild type, to that of the rapidly fatal. Three weeks ago I was called to a case, the first in the locality, which rapidly developed the most alarming indications, and despite anything I, or able council could do, the patient died within a week. Notwithstanding the malignity of the disease, and the fact that younger children, the parents, nurse, etc., had all been exposed to the contagion, thanks to the prophylaxis, or to some other cause unknown, there has been no other case of the disease in that family. As some of your readers may not have seen the article to which reference has been made, it may not be improper here to briefly restate the theory. Believing in the germ origin of the disease, I thought it reasonable that any remedy which would destroy the bacteria when developed would prevent the development of the micro organism in those who had been exposed to the infection, and therefore to all such I administer the same constitutional remedies that I exhibit to the patient. I do not assert, from the experience of seven years, that the prophylaxis will never fail, but with such encouraging results thus far, is it not our duty to continue testing it until it shall (if it ever does), prove untrustworthy?

T. R. Buckham, M. D.

Flint, Mich., June 24, 1885.

PUERPERAL ECLAMPSIA, CAUSED BY ALBUMINURIC UTERO-GESTATION

Dear Sir:—On April 6, 1885, I was called to attend Mrs. L. F., whom I found sitting up in a chair, with her lower extremities extended upon another chair, in a partial semi-reclining attitude. There was general anasarca, with an exaggerated manifestation of the condition in her lower extremities, from the core downward. I found, upon examination, that she was in an advanced stage of pregnancy, and albuminuric, and that her condition was of no little concern. I began a tonic course, with a view to improving the blood, but before there was a suspicion of maturity, owing to my cognizance of the marital date, I was no little surprised when I was sent for the next night. I found her in labor, which terminated happily with a male infant, yet not vigorously developed. I gave instructions as to the attention that was due the mother, and returned home, intending to visit her again at 9 A. M. I was called again at daylight, urgently, with information that she had had a convulsion. I found, upon reaching her bedside, that it was true, and that she had bitten her tongue fearfully.

With the albuminuric condition, the œdema of the tongue following was so great as almost to preclude her free and easy respiratory effort, and I feared at one time that I should be compelled to perform tracheotomy, but fortunately it was not necessary, notwithstanding she had convulsions at intervals for four days.

I was able to sustain her upon iced milk, for its nutritious as for its calmative influence upon the swollen tongue. I also allowed her to have crushed ice to dissolve upon her tongue. I used, by enema, a combination of chloral and bromide of potassium, by giving it freely and keeping her positively under the influence of it, save towards the more improved termination of the case. I added 30 drops tr. opii. Nutritious addenda were made to the enemata, so that her strength was fortified coincidently with the arrest of the convulsions.

Geo. N. Monette, M. D.

285 Camp street, New Orleans.

CORRECTION

Dear Sir:—In your issue of June 13, 1885, page 668, is an item that needs correction. The paragraph alluded to should read as follows: Dr. X. C. Scott moved the appropriation of $500, or so much as should be necessary to pay the necessary personal expenses of the committee appointed to advocate before the legislature of Ohio the necessity of "Medical Examiners" for this State; also, a "State Board of Health." Dr. Franklin supported the motion, saying that the Society could not expect their committee to pay their own traveling expenses, their hotel bills, for printing circulars, and paying postage, etc., out of their own pockets.

Dr. Franklin has never been a member of the legislature, and did not make the remark attributed to him by your reporter. Respectfully,

Member Ohio State Medical Society.

Chillicothe, Ohio, June 28th, 1885.

RUPTURE OF OVARIAN CYST DURING COITUS

Dear Sir:—I notice in some of the journals giving a report of the proceedings of the Surgical Section of the recent meeting in New Orleans, that I am reported as having stated in a case of ovarian cyst that during coitus the cyst was ruptured, thus causing the tumor to disappear, and with it the death of the patient. The reporter's statements are correct with a single exception: the woman survived and is now well. Yours truly,

W. F. Peck.

Davenport, Iowa, May 13, 1885.

BOOK REVIEWS

Neuralgia and the Diseases that Resemble it. By Francis E. Anstie, M. D., London, F. R. C. S., Senior Assistant Physician to Westminster Hospital, Physician to the Belgravia Hospital for Children. Sm. 8vo., pp. 233. New York and London: G. P. Putnam's Sons. 1885. Chicago: W. T. Keener.

We regret to say that the author and the publishers have followed a very bad example, which seems to be almost epidemic this year, of sending out a book without an index. We have so frequently referred to this matter during the past three or four months, that we do it again at the imminent risk of having some one suspect that we have acquired a new form of insanity, "Indexomania." But next to being hopelessly bad or pernicious, there is no fault so great in a book as the want of an index, and every one who intends writing a book, and every publisher, should believe these words and have them posted in a conspicuous place.

But aside from this, Dr. Anstie has given us an excellent book. The work consists of an introduction, on Pain in General, in two parts. The first part contains five chapters on the Clinical History, Complications, Pathology and Etiology, Diagnosis and Progress, and the Treatment of Neuralgia. The second part, devoted to the diseases that resemble neuralgia, treats of Myalgia, Spinal Irritation, the Pains of Hypochondriasis, Locomotor Ataxy, Cerebral Abscess, Alcoholism, Syphilis, Subacute and Chronic Rheumatism, Latent Gout, Colic and other pains of Peripheral Irritation, and Dyspeptic Headache. It is almost a foregone conclusion that Dr. Anstie should have written a good book on neuralgia, as will be acknowledged by those who had the pleasure of reading his contributions on this and kindred subjects in the English journals previous to his death. The presswork is not in the usual good style of the Putnams, the type is too small for entirely agreeable reading. But aside from these considerations we cannot see the utility of a reprint of a book, unchanged, fourteen years after its first appearance.

Myths in Medicine and Old Time Doctors. By Alfred C. Garratt, M. D., fellow of the Massachusetts Medical Society, etc., 8vo., pp. 242. New York and London: G. P. Putnam's Sons, 1884. Chicago: Jansen, McClurg & Co.

This book (which should have been indexed) is a very readable epitome of the history of Medicine. It is to be regarded as a luxury rather than as a necessity for the physician's library, but it is one in which very much of interest may be found. In reading the first chapter on "Eminent Physicians of Ancient Times," from Hippocrates to Galen, we are somewhat surprised to find that some of the views expressed by Galen, and which are now myths (and believed by many people) are not mentioned. For example, the curious belief that has existed since the time of Galen, that human health is largely under the influence of the moon. Galen states that animals born at the full of the moon, are strong and healthy.

This belief in the influence of the moon has been very wide spread. It is mentioned by Kuckringius and Mead, and by Martius in 1700 in his Erfurt Address, and in the time of Cockayne, who devotes considerable space to it, it was firmly believed by the leeches. It will be remembered that Sir Thomas Browne refers to the following simple method of getting rid of warts: "Go out and watch when the new moon (or full moon) is just over head. Then rub the affected hand with the other." Langham's "Garden of Health" gives an equally certain remedy. For generations and generations, the May moon has been thought, in the South of England, to have a share in curing scrofulous complaints. Henderson in his "Notes on the Folk-Lore," tells of a "cunning man" in Dorsetshire, whose charms were only potent in the month of May, and when the moon was new. Sir Kenelm Digby, in his "Discourse on the Power of Sympathy," mentions a cure for warts in which the moon is a potent factor. Galen believed that the moon governed the periods of epileptic seizures, and Mead endorsed his opinion, and he quotes from Bartholin the story of an epileptic girl who had spots on her face, which varied with the time of the moon, both in color and size. Chaucer speaks of a fever supposed to be caused by the moon, and Culpepper, in his "English Physician" tells us that the left eye of man and the right eye woman, are the privileges of the moon.

Some very interesting reading could have been made, by relating these and dozens of other superstitions and myths. The closing pages of the book, are devoted to a consideration of what may be called "The little end of nothing whittled down to a point,"—homœopathy.

ASSOCIATION ITEMS.

Dr. C. C. Frost, of Nashville, Tenn.—In the 26th number of Vol. 4, June 27th, was published the list of Delegates and members from the several states, who were in attendance at the meeting in New Orleans, April 28th, 1885. In the list from Nashville, Tenn., appears the name of C. C. Fite, M. D., which should have been C. C. Frost, M. D.

Special Notice Concerning No. 4, Vol. 3, of this Journal.—We wish again to remind all readers of the Journal who are looking over their files for binding or any other purpose, that by mistake of the former printer, number *four*, volume *three*, July 26th, 1884, had the number and date of the preceeding week, namely number 3, July 19th, 1884, retained on the outside front page. On the inside pages throughout, the *number*, *date* and pages are all correct. Therefore we wish to emphasize the request that all those who, in glancing over their files, suppose they find *two* copies of number 3, July 19th, 1884, and none of number 4, July 26th, will take the trouble to compare the numbers and dates on the first page of reading matter of the two copies, and they will readily discover, that instead of duplicates, they have the two successive numbers that they need.

MISCELLANEOUS.

Another Diphtheria Prize.—M. and Mme. Victor Saint-Paul have given 25,000 francs to the Academie de Médecine, to constitute a prize for the discovery of a remedy which shall be recognized by the Academy as efficacious in diphtheria. The prize is open to the world. Until the remedy is found, the interest on the above-named sum, will be paid every second year to those whose work or researches on the subject are considered best by the Academy.

The Cholera in Spain.—Dispatches from Madrid, of July 6, state that in the whole of Spain on July 4, there were 1,467 new cases of cholera and 660 deaths from the disease. Of these there were 219 new cases and 56 deaths in Aranjuez, 264 new cases and 144 deaths in the city of Valencia, and 680 new cases and 417 deaths in the provience of Valencia.

Cholera in Marseilles and Toulon —The United States consul at Marseilles has informed the Department of State that cholera has again appeared in that city and in Toulon A general exodus from Marseilles has begun He reports that the apparent death rate is below the average

Ferran's Proprietary Vaccination —It is stated, by the Valencia correspondent of a daily contemporary, that Dr Ferran objects to revealing his secret of cholera vaccination except for monied consideration

Study in Hygiene —Dr John S Billings, U S A , Lecturer on Hygiene in the Johns Hopkins University at Baltimore, recently gave a lecture before the officers and students of the university, outlining a course of study in hygiene He said that it should include an account of the principal causes of disease, including heredity, meteorology, the present position of the germ theory, etc , of water supply and its impurities, water analysis, methods of obtaining and storing water for use, water-waste and its prevention, the pollution of streams, the disposal of water after it has been fouled by household use, of scavenging, including methods for the disposal of house refuse and sewage, the general principles of the so-called combined and separate systems of sewerage, and their modifications, house drainage and plumbing, heating and ventilation, and of the principal application of the general principles of sanitary construction, in both private habitations and public buildings He said that every well educated man should be able to form an intelligent opinion as to the sanitary condition of a house, a school building, or a hospital A citizen is liable at any time to be concerned in the construction or management of some of these institutions, and must act in a judicial capacity upon the recommendations of people having opposite opinions, and, sometimes, opposing interests The habitations of the poorer classes, and especially tenement houses, and the best means of regulating these so that they shall not become causes of disease and immorality,—and to do this without interfering unduly with private rights, which involves not only sanitary considerations, but also some of the general principles of sociology and political economy,—should also be a subject of instruction Food and its adulterations, the special dangers and nuisances connected with certain occupations, the proper modes for caring for the dead, the subject of vital statistics, including methods for taking a census, for registration of births, marriages and deaths, and of classifying, tabulating, and publishing the information derived from these methods of preparing life tables, and of calculating expectation of life, and so much of the jurisprudence of hygiene as would enable the student to understand his own relation as an individual in this respect and those of the people to the state, and of the latter to the nation, including the general principles of laws establishing boards of health, the methods of checking the spread or importation of contagious or infectious diseases, quarantine, and the common law of nuisances were suggested as other proper subjects for instruction in such a course Dr Billings thought that the subject was worthy of study for its own sake, and, besides, that the knowledge thus gained would be decidedly advantageous to every professional man, enabling him to form an intelligent opinion as to the influence which his surroundings would have upon the health of himself and his family, to take timely steps for prevention, and to protect himself from being unnecessarily alarmed or unduly swindled by charlatans in the guise of sanitarians —*San News*, May 30, 1885

Health in Michigan —Reports to the State Board of Health, for the month of June, 1885, compared with the preceding month, indicate that cholera morbus and diarrhœa increased, and that pneumonia and bronchitis decreased in prevalence

Compared with the average for the month of June in the seven years, 1879–1885, measles, remittent fever, intermittent fever, whooping-cough, pneumonia, consumption of the lungs, bronchitis, and diarrhœa were less prevalent in June, 1885

For the month of June, 1885, compared with the average of corresponding months for the seven years 1879–1885, the temperature was lower, the relative humidity was more, and the absolute humidity, and the day and night ozone were less

Including reports by regular observers and others, diphtheria was reported in Michigan in the month of June, 1885, at 41 places, scarlet fever at 27 places, and measles at 16 places

Professor H Newell Martin, of Johns Hopkins University, has been elected a Fellow of the Royal Society of England

State Board of Health of Pennsylvania —The Governor of Pennsylvania has appointed the following, to act as members of the State Board of Health Col William Ludlow, Drs Benjamin Lee, Joseph F Edwards, and Pemberton A Dudley, of Philadelphia, E W Germer, of Erie, and J W McClellan, of Pittsburgh

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U S ARMY FROM JUNE 27, 1885 TO JULY 3 1885

Major H E Brown, Surgeon, assigned to duty as post surgeon, Fort Reno, Indian Ter (S O 91, Dept Mo , June 24, 1885)

Captain F C Ainsworth, Assistant Surgeon, relieved from duty at Hdqr's Dept Mo (S O 93, Dept Mo , June 26, 1885)

Captain B D Taylor, Assistant Surgeon, assigned to duty at Little Rock Bks , Ark (S O 139, Dept East, July 1, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING JULY 4 1885

Shafer, Joseph, Assistant Surgeon, for duty on board the U S receiving ship "St Louis," League Island, Penn , July 10, 1885

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED JUNE 27 1885

Long, W H , Surgeon, granted leave of absence for three days, June 18, 1885

Fessenden, C S D,, Surgeon, leave of absence extended seven days on account of sickness, June 24, 1885

White, J H , Assistant Surgeon, granted leave of absence for twenty one days, June 23, 1885

BLOOD, AND HOW TO MAKE IT, FAT, AND HOW TO REDUCE IT.[1]

BY BENJAMIN LEE, A.M., M.D., PH.D.,
OF PHILADELPHIA, PA.

The valuable and suggestive little treatise whose title I have partially borrowed as the heading of this paper, contains, in my judgment, together with very much that is useful, suggestions of lines of treatment which are open to serious objection, and which, in other hands than the author's, are capable of producing injury rather than benefit. The essential feature in his management of the class of nervous and hysterical valetudinarians which he considers in the work referred to, is the systematic employment of *Massage* and the *Movement Cure*. The enforced *rest*, the characteristic which impresses itself upon the popular mind, and which has given the name to his system is, apart from its influence on the *morale* as a means of subduing the perverse will of a spoiled child, simply an accident of the massage and the acto passive exercise, necessary to a certain extent in order to reap the full benefit of those methods, not necessarily remedial in itself, and, without them, as likely to do harm as good.

The *over-feeding* which is another portion of his plan much insisted on, is only made possible by the mechanical treatment mentioned, and but for that must prove in the highest degree pernicious. Even with this precaution, there is room for doubt whether it may not overload the emunctories to a degree entirely beyond their capability to take care of the unassimilated material, forced upon them in order to build up the adipose tissue. But even if we have succeeded in this attempt, and have plastered over the muscles and bones with a liberal layer of fat, we can be by no means sure that it will stand the wear and tear of real life and will not, with the return to home duties and cares and fatigues, "consume away like the fat of lambs." Of all the words of wisdom contained between the covers of the little treatise referred to, not one of them is at once more sententious and more truthful than the remark of that delightful old nurse that "some fats is fast and some fats is fickle, but cod-oil fat is easily squandered."

We can not be sure, however, that the carbon supplied so much in excess of the demand will be stored up exactly where we design it to be, that it will obediently take its place on the outer surfaces of the muscles, and form a graceful layer beneath the integument, and not rather deposit itself interstially in the muscular tissue, enfold the heart in a stifling blanket, or permeate the liver from capsule to gall-duct. When in charge of the hospital of the Colored Home in New York, during my student days, it was my fortune to see much of fatty degeneration, both as detected during life in the *arcus senilis*, and the tones of the flabby heart, and as revealed in the glandular organs by the autopsy. And I have not changed the opinion then formed that its frequent occurrence in that race was owing, in part at least, to the large quantities of fat pork consumed by them. The Italian ortolan, seduced by supposititious sunrises into taking five meals a day, is not as happy or lively a bird as his American cousin the bobolink, which feeds but twice. A Strasbourg goose is certainly not the synonym of health and vigor, and however tempting a *pate de foie gras* may be to the palate of the epicure, the livers which compose it were anything but a source of comfort to their original owners. Life which depended on such livers was certainly not worth living.

What constitutes the firm, elastic flesh of a healthy infant, or the exquisite lines of embonpoint in a beautiful woman is not so much the layer of fat underlying the skin, as *capillary tone* in the *rete mucosum*, in the fat itself, and in the muscles.[1] Take away that essential element, and the skin either shrinks into the rigid wrinkles of collapse, hangs in the flabby folds of inanition, or puffs up in the shapeless tumidity of œdema. Who has not had the sad experience of seeing a baby one day as plump and rotund as a study of Murillo, and the next with the sunken eye and hollow cheek of cholera infantum? And yet will any one claim that in that brief interval there has been any material loss of adipose tissue? Is it not simply that the fluids have been drained away, especially from the surface, that the capillaries are empty, and the superficial vessels are in a state of collapse? Hence I hold that in these cases of impaired nutrition, hydrated blood, degenerated tissue and depressed nerve force, our

[1] Burdon Sanderson says: "The capillary is not a dead conduit, but a tube of living protoplasm." Kirke says: "The capillaries must be looked upon not as mere passive channels for the passage of blood, but as possessing endowments of their own (vital capillary force) in relation to the circulation. The capillary wall is actively living and contractile, and there is no reason to doubt that, as such, it must have an important influence in connection with the blood current."

BLOOD, AND HOW TO MAKE IT, FAT, AND HOW TO REDUCE IT[1]

BY BENJAMIN LEE, A M, M D, PH D,
OF PHILADELPHIA PA

The valuable and suggestive little treatise whose title I have partially borrowed as the heading of this paper, contains, in my judgment, together with very much that is useful, suggestions of lines of treatment which are open to serious objection, and which, in other hands than the author's, are capable of producing injury rather than benefit The essential feature in his management of the class of nervous and hysterical valetudinarians which he considers in the work referred to, is the systematic employment of *Massage* and the *Movement Cure* The enforced *rest*, the characteristic which impresses itself upon the popular mind, and which has given the name to his system is, apart from its influence on the *morale* as a means of subduing the perverse will of a spoiled child, simply an accident of the massage and the acto passive exercise, necessary to a certain extent in order to reap the full benefit of those methods, not necessarily remedial in itself, and, without them, as likely to do harm as good

The *over feeding* which is another portion of his plan much insisted on, is only made possible by the mechanical treatment mentioned, and but for that must prove in the highest degree pernicious Even with this precaution, there is room for doubt whether it may not overload the emunctories to a degree entirely beyond their capability to take care of the unassimilated material, forced upon them in order to build up the adipose tissue But even if we have succeeded in this attempt, and have plastered over the muscles and bones with a liberal layer of fat, we can be by no means sure that it will stand the wear and tear of real life and will not, with the return to home duties and cares and fatigues, "consume away like the fat of lambs" Of all the words of wisdom contained between the covers of the little treatise referred to, not one of them is at once more sententious and more truthful than the remark of that delightful old nurse that "some fats is fast and some fats is fickle, but cod oil fat is easily squandered" We can not be sure, however, that the carbon supplied so much in excess of the demand will be stored up exactly where we design it to be, that it will obediently take its place on the outer surfaces of the muscles, and form a graceful layer beneath the integument, and not rather deposit itself interstially in the muscular tissue, enfold the heart in a stifling blanket, or permeate the liver from capsule to gall-duct When in charge of the hospital of the Colored Home in New York, during my student days, it was my fortune to see much of fatty degeneration, both as detected during life in the *arcus senilis*, and the tones of the flabby heart, and as revealed in the glandular organs by the autopsy And I have not changed the opinion then formed that its frequent occurrence in that race was owing, in part at least, to the large quantities of fat pork consumed by them The Italian ortolan, seduced by supposititious sunrises into taking five meals a day, is not as happy or lively a bird as his American cousin the bobolink, which feeds but twice A Strasbourg goose is certainly not the synonym of health and vigor, and however tempting a *pate de foie gras* may be to the palate of the epicure, the livers which compose it were anything but a source of comfort to their original owners Life which depended on such livers was certainly not worth living

What constitutes the firm, elastic flesh of a healthy infant, or the exquisite lines of embonpoint in a beautiful woman is not so much the layer of fat underlying the skin, as *capillary tone* in the *rete mucosum*, in the fat itself, and in the muscles[1] Take away that essential element, and the skin either shrinks into the rigid wrinkles of collapse, hangs in the flabby folds of inanition, or puffs up in the shapeless tumidity of œdema Who has not had the sad experience of seeing a baby one day as plump and rotund as a study of Murillo, and the next with the sunken eye and hollow cheek of cholera infantum? And yet will any one claim that in that brief interval there has been any material loss of adipose tissue? Is it not simply that the fluids have been drained away, especially from the surface, that the capillaries are empty, and the superficial vessels are in a state of collapse? Hence I hold that in these cases of impaired nutrition, hydrated blood, degenerated tissue and depressed nerve force, our object should not be to overload the economy with carbon and lay on layer after layer of adipose tissue, but to create a demand in the tissues farthest from the centre for healthy blood, by breaking down and forcing out the dead-alive cells with their accumulation of morbid deposit, and sending them to the emunctories to be excreted, and, as this demand begins to be felt, supplying it cautiously—principally with nitrogenous elements—and not in excess of the ability of the assimilating organs to manage it.

---

[1] Read in the Section on Practice of Medicine Materia Medica and Physiology at the Thirty sixth Annual Meeting of the American Medical Association

[1] Burdon Sanderson says The capillary is not a dead conduit but a tube of living protoplasm Kirke says The capillaries must be looked upon not as mere passive channels for the passage of blood but as possessing endowments of their own (vital capillary force), in relation to the circulation The capillary wall is actively living and contractile and there is no reason to doubt that, as such it must have an important influence in connection with the blood current'

In this way we shall build up the system, atom by atom, cell by cell, each tissue appropriating its peculiar aliment, and no one being nourished at the expense of another. In this way we may hope to develop a gain in weight, and a plumpness, which will outlast the hot-house period of enforced rest, since it will depend not upon a superficial layer of poorly condensed oil, but upon a capacity of all the tissues to retain a sufficient amount of blood in their vessels, and of lymph in their intervascular and areolar spaces, as well as upon an increase in both the number and the solidity of the cells composing them. The particular tissue in which we should look for greatest gain in this respect is the muscular, first, because it has usually been the most neglected in these cases, and suffered the most serious degeneration, and secondly, because it is the most intimately connected with the blood making process. I do not know that we should go very far wrong if we assigned this process in part as one of the functions of muscle. Constituting as it does, with its appurtenances, almost one-third of the entire man, and being, moreover, extremely vascular, it is not too much to suppose that under ordinary conditions it contains one half of the blood of the tissues, and under conditions of great activity, considerably more. It is the grand blood reservoir of the system, far surpassing the spleen in this character, and capable of infinitely greater expansion, under the necessity of great stress. But it may be that it is more than a reservoir, and that with its frequent force-pump action of contraction and relaxation, it is inviting the circulating fluid into itself not simply for the selfish use of self nutrition, but to prepare it for its purposes as a nutrient for other tissues. Certainly, if each tissue, in appropriating to itself the elements necessary for its own growth, is an excretory organ in its relation to all other tissues, as has been sagaciously observed, then the muscular tissue, from its immense preponderation of bulk and weight over all the other organs and viscera (excepting the bones), must be admitted to have most important uses, at least in eliminating materials which would be noxious to other portions of the economy. And daily experience combines with the results of scientific analysis to indicate this as one of the most important results of exercise. The following history will serve to illustrate my meaning.

In the winter of 1867 I was requested by Mr. J. S. to visit his daughter, living in one of the suburbs of Philadelphia. She had been confined to the bed for seven years, and he described her condition as so desperate that I felt sure that nothing could be accomplished in her case without the most assiduous personal attention. As it seemed impossible to bestow this at such a distance, and as I knew that she was in the hands of skilful practitioners, I represented to her father the difficulties of the situation, and respectfully declined to see her. The following day, however, he returned armed with so urgent a request from the attending physicians that I had no longer a right to resist his earnest solicitations. I accordingly saw her in consultation with the family physician and the consultant, on the 18th of December.

The following is a brief *resume* of her history up to that time. Her parents, both of them living, were of decidedly nervous temperament. As an infant she was so feeble and ill-nourished that it was not supposed she would live to adult life. As a child she continued to be delicate, able to undergo but little fatigue, and having a poor and irregular appetite. Menstruation was established at the age of fifteen, and a year later her debility began to increase rapidly, being especially marked in the morning, and it was noticed that her face and her feet were swollen on awaking. Pain in the back, extending through to the chest and epigastrium, now made its appearance. This was much increased by the pressure of her clothing. Blisters and other counter-irritants gave temporary relief. This condition continued with variations for four or five years, gradually becoming more serious. Her temper became very irritable, motion caused great pain, and locomotion was in consequence almost entirely given up for a time. There was then a period of slight improvement, but the pain frequently returned, usually ushered in by febrile symptoms. She suffered from almost constant nausea and frequent attacks of water brash. Menstruation was very painful. At first too frequent, it subsequently became the reverse, and was supplemented by vomiting of blood and discharge of blood from the mouth, apparently from the gums or mucous membrane. Finally it ceased altogether, and symptoms of grave nervous derangement supervened.

She became subject to violent hystero cataleptiform seizures, characterized by strong opisthotonos, rigid contraction of the extremities, and facial contortions. These alternated with fits of hysterical mania, during one of which she attempted suicide by throwing herself from a window. Her screams during these attacks could be heard for a long distance from the house. The seizures were almost invariably followed by sick headache, with very violent vomiting. Such was the state of things during the years 1861 and 1862. During the latter part of this period she took to her bed, and had not been able to walk since. During the summer of 1867 she was taken to Atlantic City, on a bed in a baggage car. While there persistent vomiting set in, at first recurring every ten or fifteen minutes, but gradually diminishing in frequency. This continued incessantly for four months, at the end of which time she had become excessively emaciated and so weak as to be unable to raise her eye-lids. Her eyes were now very sensitive to the light. As the irritability of the stomach diminished the irritation appeared to be transferred to the lower extremities, which began to draw up toward the body, while at the same time there was a sensation as of red hot needles piercing the feet. When the contractions became complete these sensations ceased, and the soles of the feet became at once anæsthetic and hyperalgesic. She compared them to "sensitive sponges." This condition had existed for about two months when I first saw her. My entrance into the room was greeted by a piercing shriek, and this was the only notice that the patient took of me during the entire visit, save that I could detect a slight muscular tremor in obedience to my command that she should move her hand as I held it in my own. She was emaciated to the last degree. Her face was pallid and her lips bloodless. The gums were spongy and bled at the slightest touch. Her lower lip was drawn under the teeth of the upper jaw, and forced against them with a rapid motion. Her hair was in a solid mat at the back of her head, it having been impossible to comb it for months. The hands were flexed on the wrists, the thumbs strongly adducted across the palms and the fingers clinched over them. The decubitus was almost dorsal for the head and shoulders, but the lower part of the body was twisted to the left, so that the position of the legs was lateral. The lower extremities were in a state of complete contraction, the knees almost touching the chin, the heels close to the buttocks, the feet in a line with the legs, and the toes bent under the sole, until the long toe nails were imbedding themselves in the flesh. The legs were also, much of the time, in active spasmodic motion, so that as they lay upon their sides notwithstanding the fact that they rested upon a water cushion, the external malleolus of the left and the internal malleolus of the right had become excoriated by the friction, and presented deep ulcers. The entire limbs were so painful to the touch that it was necessary to support the bed clothes on a hoop. There was also excessive pain in the abdomen and stomach.

To relieve this suffering she was taking enemata of large doses of morphia (I have mislaid my memorandum of the amount and do not venture to state it from memory), every two hours. She was unable to turn herself in bed, and could not bear to be touched, so that when occasion required she was turned on a sheet. For a long time she had evacuated the bowels only once a week, and that with the aid of an enema, laxatives having lost all effect. This operation was always followed by severe vomiting and great prostration. She had frequent distressing spells of hiccough and of protracted yawning. Menstruation had been completely suspended for four or five years, but she was still conscious of a sensation of being excessively swollen at the menstrual epoch. There was a very considerable right lateral curvature of the spine. She was living principally on stimulants (champagne, brandy, and Hoffman's anodyne), taking very little in the way of food.

In the consultation following my examination, it was agreed that the contractions and spasms were of reflex rather than of spinal origin, probably having their source in the reproductive organs, that the spinal curvature was of secondary importance, although not to be overlooked as an element in the case, and that the only hope was in restoring the capillary circulation in the extremities, stimulating tissue metamorphosis, and thus exciting a demand on the part of the system for food, which would then be appropriated and make healthy blood, for it was evident that she was anæmic to the last degree. The case was kindly consigned to my entire charge.

I at once instituted a course of massage and Swedish movements. It was at first addressed to the hands and feet alone. At the first visit the hands only were treated. Kneading was begun at the tips of the fingers, and extended up to the wrist. Passive movements were then made of the terminal phalanges, and successively of the others in turn, then of the entire fingers, and finally of the hand on the wrist. When an evidence of slight improvement in the circulation was given by increased warmth, more vivid coloration, and diminished rigidity of the joints, the patient was ordered to make slight voluntary movements of the fingers against slight resistance on the part of the masseuse, and in her turn to oppose all the resistance of which she was capable to the movements of the former. She was of course obstinate at first, and obeyed most unwillingly, but the constantly repeated injunctions of the attendant, aided by the force of her will, and the sense of control imparted by the movement of her muscles without the consent of her own volition, triumphed, and after a few sittings all opposition was overcome. After she had become somewhat accustomed to the mode of making the hand movements, the same course was begun with the feet. These were very cold, and livid up to the ankles, without the slightest indication of circulation. The ends of the toes were first treated. Considerable force was needed to overcome their contraction, and at first they returned at once to their flexed position. But each application found them less rigid, and the surface of the feet less sensitive. After half a dozen seances, I felt convinced that I could see a little evidence of a return of the blood to the superficial capillaries, and considered myself justified in announcing to her father that her improvement had begun.

I may remark just here, that in these cases of enfeebled muscles and perverse will, it is important in administering the acto-passive movements, first, never to direct a motion to be made to which there is any insuperable mechanical obstacle, and secondly, always to insist on the motion being made to the full extent indicated. If the patient voluntarily resists, that resistance must be abolutely overcome. Nothing so much aids in subjecting the will of the patient to that of the medical adviser and his assistants as a consciousness of powerlessness in his and their hands. If, on the other hand, the patient honestly strives to make the required motion, and has not sufficient strength to accomplish it fully, the masseur must aid in its completion. A skilled operator will do this so naturally and gently that the patient will not suspect that aid is being given, and, pleased with the success of his effort, will thus be stimulated to repeat it with increased vigor. This is a pious fraud, perhaps, but certainly one which may be regarded with lenience.

One of my first aims in the management of this case was to diminish the amount of morphia and of stimulus which she was taking, for I felt sure that the former was drying up all the secretions and paralyzing her vegetative life, while the latter substituted more nutritious food and destroyed the appetite for it The former was the more difficult to control, inasmuch as she invariably insisted on having the dose weighed out before her eyes, and the recurrence of pain as the influence of the drug wore off made her always alert to call for it at the end of the two hours I endeavored to combat its effects by the administration of atropia, but here I was foiled by a most extraordinary sensitiveness to the poisonous action of that drug The first dose of 1–120 gr produced truly alarming effects, and when, after reducing it to the 1–480 gr, I still found dilated pupils, dimness of vision, and scarlatinal rash, I concluded that it was not wise to attempt to overcome the intense dread of its effects which had taken possession of her I am obliged to confess that in order to accomplish my end, I found it necessary to tamper with the scales The amount was thus gradually reduced, at first without her knowledge, subsequently, when she became more amenable to reason, with her cooperation, until the use of the drug was entirely abandoned, and she came to look upon it with such horror that at her urgent request I abstained from ever again prescribing it for her

The *treatment was continued somewhat irregularly* for two months, when it was unavoidably interrupted by the serious illness of another member of the family, and was not resumed until the end of the following September, when I insisted on her being removed to the city in order that it might be carried out more effectively in all its details I now placed her in charge of one of my most competent masseuses as her nurse and attendant, and prescribed all the minutest details of her daily life, requiring everything to be done by the watch Under this regime her improvement was steady, though not rapid Her muscles gradually increased in volume, and her nerves in endurance She was able to bear both light and noise better, and the painful sensitiveness of the feet diminished

By the month of February, the contractions, which it will be remembered had held her shut up almost like a closed knife, had so far yielded that slight pressure would bring the feet to a right angle with the legs, and the flexion of the knees was so much reduced that I could apply a pair of steel knee-braces These I had put on every day and worn for a certain length of time, and as soon as she became sufficiently accustomed to the pressure, I placed her daily in the standing position, with her hands on my shoulders and a broad girth passed around her body and my own at the level of the hips, in order to maintain her erect with as little effort on her part as possible These attempts were at first followed by hystero-cataleptic attacks convulsions, unconsciousness, rigidity or hysterical screaming But these gradually wore off as the efforts were persisted in and the contractions relaxed

The following summer she had sufficiently recovered to be able to go to the mountains, and while there began to walk with the aid of her attendant, without the support of the knee braces Below is the schedule which I placed in the hands of her nurse on leaving, to show the manner in which her day was portioned out This was adhered to faithfully unless she was suffering in some unusual manner

DAILY PROGRAMME FOR MISS ——

Breakfast	8 30	to	9 00
Rest	9 00	"	9 30
Toilet	9 30	"	10 15
Rest	10 15	"	10 45
Bath	10 45	"	11 00
Rest	11 00	"	11 30
Dressing	11 30	"	12 00
Rest, Lunch	12 00	"	1 00
Movements	1 00	"	2 00
Rest	2 00	"	4 00
Dinner	4 00	"	5 00
Ride, visits, etc	5 00	"	7 00
Tea	7 00	"	7 30
Reading and amusement	7 30	"	9 30
Retiring	9 30	"	10 00
Taps	10 00		

The toilet after breakfast was that of the bowels, a daily enema being necessary This she had been in the habit of receiving on awakening in the morning, before taking food But considering that this was unnecessarily exhausting, I induced her to change the hour, which she did with great reluctance The bath included sitting in a shallow bath, slightly cool, and the use of a vaginal syringe The bath was at a temperature of 112° F on entering, and gradually cooled down to 80° F before leaving it, and was to be continued not longer than 15 nor less than 10 minutes Under the influence of abdominal massage, and movements of flexion and adduction of the thighs, her menses had returned during the spring, after a period of total cessation of about six years In order to stimulate this function and relieve dysmenorrhœa, as well as to calm nervous excitement and improve the circulation in the lower extremities, I used the spinal ice bag to the lumbar spine and upper part of the sacrum once every day for half an hour, ordinarily and twice a day before and during the menstrual epoch I believe that this simple method of treatment for such conditions is not sufficiently appreciated as it should be by the profession

As she was now able to be for a considerable part of the time in the upright posture, the lateral curvature of the spine, of which mention has been made, became a factor of considerable importance in her sum total of disabilities I therefore, in November, soon after her return from the mountains, applied an instrument with a strong ratchet movement to give support to the spine, and overcome the deformity as far as might be At this time she came to stay for the winter in my private hospital, in order to avail herself of the use of the machinery of my Treatment Hall, designed especially for giving appropriate exercises in this form of curvature She now improved rapidly in walking, and was soon able to take short walks out of doors

It is unnecessary to detail the case further Side issues were met by appropriate remedies as they pre sented themselves. Hæmorrhages, endometritis, uterine malposition, etc., needed much attention, but the general outcome was restoration to the duties of life, which she has since discharged with great faithfulness, and to the pleasures of society, which her naturally brilliant mind fitted her to adorn.

Now what was the efficient agent in this case in breaking up the chain of morbid processes, in promoting tissue-metamorphosis, in stimulating nutrition and consequently in making blood? Not *rest*, certainly, for that she had been taking *ad nauseum* for months and years before I saw her. Not *over feeding*, for I was never very urgent that she should take much more food than her appetite called for, and that was at no time large. No, it was simply so acting upon the fluids in the blood-vessels, the lymphatics, and the areolar lymph spaces by purely mechanical means as, first, to hasten the dislodgement of effete cell elements, and their absorption into the general circulation, thus creating a necessity on the part of the ultimate cells of the tissues operated on for more food, that is to say, appetite, next, to stimulate the capillaries to more vigorous action to supply this felt want of the tissues, then to arouse the muscular tissue to the performance of its double function of accelerating the blood and lymph currents, so necessary to wash away the detritus, and of carrying on that decomposition and recomposition of the blood which is essential to make it a vitalizing agent for glandular tissues, and finally to evoke the activity and restore the equilibrium of these glands themselves secretory and excretory, superficial and deep seated.

But while there is room to doubt whether a rapid increase of fat is ever an advantage, and whether any addition to the adipose element of the individual beyond his natural percentage of this tissue as compared with others, is not a positive injury, there can be no question that its excessive accumulation, whether all over the surface, in the abdominal walls, or in the omentum, is a calamity, and a grave one. Fat being a non-conductor, prevents, so I have thought, the internal fires from radiating their warmth to the integument, wherein reside the sensations of heat and cold. It is undoubtedly an admirable arrangement for the bear, protected on the one hand by his winter surtout of fur, and confined to the unchanging atmosphere of his close cave, and on the other entirely oblivious in his profound slumber, of all external changes and superficial sensations, to have his fires thus banked up and slowly fed for months together, and thus maintain the temperature of his interior somewhat at the expense of the surface, but the plan works by no means so well in the non-hibernating human being. In my observation it is not true that fat people suffer less from cold than thin people. On the contrary, it has seemed to me that the surface of the skin overlying large deposits of adipose tissue is apt to be both objectively cool, imparting less sense of warmth to the touch, and subjectively chilly, the individual requiring more clothing to make her comfortable than another who is less liberally covered by nature. That, on the other hand, the obese suffer more from heat than their thin neighbors, no one will for a moment deny. Aeration of the surface does not appear to take place so readily with them, radiation of body heat is slower, respiration is more laborious, the heart is compelled to work harder in order to distribute the blood over so great an increase of area, locomotion is greatly impeded, and the whole expression is one of anxiety.

> "Oh! that this too, too solid flesh would melt!"

is a sentiment often to be read in the faces of such sufferers. To this class belongs the following case.

On June 23, 1875, I was waited upon by a lady, residing a few miles out of Philadelphia, with the request that I would call and see her daughter, supposed to be suffering from a spinal affection which rendered her quite helpless. She described her as able to walk with great difficulty, partly from loss of power in the legs and partly from her great weight although she was only seventeen years old. Once a day, supported by two persons, she was helped down stairs, and then wheeled out on to the piazza, when the weather would permit, and there sat to get the air. This was the only exercise she was capable of taking. She suffered much from pain in the back. Menstruation was not very painful, but profuse, and there was considerable leucorrhœa. I at once informed her mother that my belief was that the true seat of her daughter's disease was the womb, and not the spine, and that I could only consent to call on her with the understanding that I was to be allowed to make a complete examination of that organ, both digital and with the speculum. This permission being somewhat reluctantly granted, I saw the patient on the afternoon of the same day.

I found a leukophlegmatic girl, of large frame, decidedly above the average height, and enormously fat. Her arm was larger around than the thigh of an ordinary adult woman, and the accumulation of fat upon the abdomen was immense. Some idea of her size may be formed from the fact that when, some months later, I walked with her in the streets of Philadelphia, her weight having been then greatly reduced, she was an object of remark to all passers by. The spinal muscles were quite unequal to the task of holding her erect in sitting, and were sensitive in consequence of the great strain which such efforts put upon them, but there was no spinal rigidity or other evidence of spinal disease, beyond a slight lateral curvature, which I considered of no account in estimating her case. There was no paresis and no contraction of the lower extremities, simply excessive debility. She lost breath on the slightest exertion, and the heart's action was weak and labored. She was pallid, the lips were pale, and the muscles were soft and flabby.

The vaginal examination disclosed a womb of about double the natural size, retroverted and partially prolapsed, and with a very patulous linear os of about an inch in length, from which exuded freely a thick albuminous discharge. There was very little tenderness of the uterus on pressure, and little sensitiveness on the introduction of the sound, but considerable ovarian tenderness. I at once instituted a course of local treatment, the main features of which were the application of fuming nitric acid to the fundus, reposition by the sound, and support of the replaced organ by a Hodge's lever pessary, which was eventually entirely successful in restoring the organ to a normal condition But our concern now is with the disposal of the immense mass of hydro carbon which was evidently an insuperable obstacle to her ever again resuming her old habits of activity I placed her, of course, on a restricted diet, limiting her closely in sugars, starches and fats, but endeavoring to allow her sufficient variety not to deprive eating of all zest I also gave her the following prescription, which she took faithfully, with occasional intervals It will be observed that the amount of liquor potassæ given was very large This could only be administered by diluting it generously

℞ Ext fuci vesiculosi fluid
Liq potassæ aa f℥ij
Aq calcis f℥xij M
Sig A tablespoonful, in a tumbler of water thrice daily, gradually increased to two tablespoonfuls

But what I most relied on to effect the absorption of the fat was the daily application of massage, and in prescribing the mode in which it was to be given I was guided by the following principles The first object was to stimulate the great emunctories, and in this way provide an outlet for the fatty detritus which I proposed to send on to them later First among these I considered the liver and the intestinal epithelium, the former, not indeed so much for the amount of excrementitious matter which it is capable of throwing out of the system as for the usefulness of its secretion as a scavenger in sweeping away the *debris* of epithelial desquamation, uncovering the outlets of the excretory ducts and stimulating the renewal of their cells Vigorous massage of the abdomen was therefore the first indication To have begun with movements of the extremities, as in the previous case, would have been to force a turbulent and muddy stream onwards to a reservoir with insufficient outlets, and would only have resulted in damming up the effete current, damaging the sluice gates and leaving morbid deposits in the glands of the abdomen But by stimulating the nerve centres of the abdominal cavity, by means of the reflex and electrical influences of rapid superficial massage and following this up with deep and forcible kneading, the excretions of the intestinal mucous membrane were first augmented, and the peristaltic action was then accelerated to carry them off

Strong percussion over the liver with the full palm of the hand, known as *liver clapping*, then followed, for the purpose at once of increasing the activity of the hepatic secretion and of mechanically hurrying the bile through the gall duct and out into the intestinal sewer Then, in order to bring the re-inforcing power of the spinal chord to the aid of the splanchnic and sympathetic nerves, rapid percussion of the spine with the last phalanges of the fingers was resorted to, beginning at the base of the brain and continuing down to the sacrum, giving especial attention, however, to the lower half of the dorsal column This was followed by a stroking of the spine and back generally, in order to soothe any irritation of the general nervous system that might have been produced, and the prescription was concluded by a few vigorous duplicated flexions and extensions of the thighs, the patient and the masseuse alternately moving and resisting, with the view of compelling the abdominal muscles to contract strongly, and also, by the action of the psoas and iliacus muscles, to stimulate the pelvic circulation and overcome the atony of the bowels

As it was not convenient for her to be moved into the city at that time, her maid, a very intelligent young woman, was sent into my treatment hall to take a few lessons of my manipulator, and as I visited the patient once or twice a week I was enabled to superintend the massage, and correct her defects of manipulation Although her method was crude, and far from satisfactory, it was so far effective that in six months, that is, from the commencement of the treatment, the patient had lost probably one third of her weight and was able to walk with some comfort

Anxious, however, for more rapid improvement she now moved into the city, and after a week of daily treatment by an experienced masseuse, was able to walk with assistance from her boarding place to the treatment hall, a distance of one square, or a twelfth of a mile By means of apparatus I was then able to give her more vigorous movements than any she had yet taken, especially rapid and powerful vibrations of the extremities, abdomen and liver Her great weight, however, being still an impediment to locomotion, and the fatigue which it caused, a drain on her nerve force, I thought it wise to relieve the spinal muscles from strain by affording them mechanical support The form which appeared to me most suitable to her case was a Banning's brace, with an extra large abdominal supporter At the same time I substituted for the Hodge pessary the retro uterine prop of the Banning brace, having its point of support external to the body from the abdominal plate This combined support at once enabled her to move with greater ease and freedom and to remain longer in the erect posture Her spirits, which had been much depressed, now began to rise, and her color gradually became more vivid and natural

The Movement Cure was continued for three months, when she returned to her home, lightened in heart as well as body, and able to walk half a mile without fatigue I continued to see her at long intervals, in order to maintain the adjustment of her mechanical appliances, and found her weight constantly diminishing and her strength correspondingly increasing There were occasional drawbacks to the latter from a prolapsus ani with hæmorrhages, which, however, yielded to astringents and appropriate support in treatment

Some time during the following spring I was surprised to have her come into my office with the announcement that she had walked in from her home in the country, a distance of six miles In fact so active was she that I was obliged to confiscate her pedometer in order to impress upon her the fact that there was a limit to her endurance, and that she was in danger of bringing on her old troubles again. A walk of ten miles she regarded as a very moderate effort. Her figure soon became as remarkable for its lightness and grace as it had before been for its shapeless and unwieldly immensity.

COLO-PROCTITIS TREATED BY HOT WATER DOUCHE AND DILATATION OR DIVISION OF THE SPHINCTERS ANI.[1]

BY ALEX. Y. P. GARNETT, M.D.,

EMERITUS PROFESSOR OF CLINICAL MEDICINE IN THE NATIONAL MEDICAL COLLEGE, WASHINGTON, D. C.

In presenting the following cases intended to illustrate the special merit claimed for the plan of treatment recommended, I fully recognize the importance of confining myself to that particular form of disease which the clinical history of each case will demonstrate, and to differentiate it from those more formidable and graver affections such as deep-seated corroding ulcers, the various forms of stricture, and varieties of cancer which are met with in rectal diseases. Whilst the disease under consideration is usually of long standing, or chronic in its character, it is a pure non-malignant inflammation, confining itself almost entirely to the mucous or sub-mucous tissues, and resulting in some cases in small superficial necrobiotic ulcerations found just within the external sphincters; that such cases are often mistaken for simple dysentery and unwisely treated by injudicious medication as such, I have no doubt.

Case 1.—In the fall of 1875 I was requested to take charge of a man about 30 years of age, affected, as he stated, with chronic diarrhœa. He informed me that he had been suffering with the disease for more than two years; that prior to the appearance of this trouble he had enjoyed excellent health, and for the last fifteen years been occupied on board a small fishing boat plying between Washington and the Chesapeake bay, engaged in the oyster trade. His family record showed no taint of strumous or tubercular disease. Upon a careful examination of this man, I found that his disease consisted in a chronic catarrh of the large intestine, extending into and embracing a greater portion of the mucous lining of the rectum. I became satisfied, from a careful manipulation, that the disease did not embrace the ascending colon, but seemed to commence in its transverse portion and proceed downward. At the time of my first seeing him there was much tenderness along the bowel, almost constant pain, always greatly augmented by defecation, usually passing of large quantities of mucus in long bands, sometimes tinged with blood, at other times there would be muco-sanguineous stools mixed with small quantities of fæcal matter. There had been frequent discharges of clotted blood at various times, exhibiting the appearance of pure hæmorrhage. The history given me of the treatment which had been pursued by the different medical gentlemen whom he had consulted, embraced most of the usual remedies employed in chronic diarrhœa and dysentery. It is not necessary to enumerate them. I directed a suspension of all medication by the mouth, confined the man exclusively to hot milk diet, and ordered an enema consisting of four ounces of strong decoction of ipecacuanha root, and twenty drops of tincture opii, to be thrown up the bowel as hot as possible, and repeated every eight hours, to be kept in bed and allowed nothing else but the hot milk as nourishment. The enemata not to be used after midnight until eight o'clock the following morning. This practice was continued for two days, when the tincture opii was reduced one-half, ten drops being employed every eight hours instead of twenty.

The patient seemed to improve manifestly from the second day after he was placed under this treatment, and continued to do so until the sixth day, when he had a return of hæmorrhage, discharging about four ounces of clotted blood. Suspecting the presence of ulcers within the rectum, a careful exploration was made by means of the speculum, but no ulcer discovered; I found, however, a proliferation, or thickening of the mucous membrane just within the sphincters, and extending for two inches or more up within the bowel. This morbid growth consisted of exuberant villosities, exceedingly vascular and soft, and feeling to the touch like thick velvet. A very close inspection failed to disclose the presence of fissures. I recollected having treated a similar case, which came under my care many years previously, by the application of nitrate of silver first, and subsequently of nitric acid, which, however, had not resulted in a cure. I determined, therefore, to try the plan of dilating the sphincter freely by pressure with the thumbs and tearing up and squeezing out the blood of the villous vegetations, and thus destroy them by cutting off the abnormal blood supply, at the same time continuing to use the hot water injections, consisting now of the solution of boracic acid, instead of the decoction of ipecac, adding the tincture opii only to the one used at bed hour, in the quantity of twenty-five drops. Injections were ordered to be administered every three hours during the day up to twelve at night. Continuing this plan of treatment and confining my patient to the hot milk diet, with an occasional slice of stale bread, I had the satisfaction of discharging him perfectly cured at the end of fifteen days.

Case 2.—Two years after the above case, in the summer of 1877, a married lady, the mother of three children, came under my care suffering with severe proctitis associated with several small but exceedingly painful fissures. This lady had suffered for many months with attacks of dysentery, which had been temporarily relieved by medical treatment, but invariably returned without any immediate exciting cause that she could discover. Latterly she had experienced several hæmorrhages from the rectum, and found that all efforts at defecation were attended with such exquisite pain that it was almost impossible for her to accomplish that act. The pain had within a few days become persistent and unceasing, rendering sleep impossible, and her existence miserable in the extreme. The dejections had for several months prior to this condition of affairs consisted largely of mucus, sometimes, but not always, tinged with blood It was impossible, in consequence of the extreme tenderness of the parts, to make a speculum examination, or even introduce my finger without first placing her under the influence of some anæsthetic, so I determined to etherize her the following day, and divide the external sphincter at once, relying upon the hot water injections for subsequent treatment

---

[1] Read in the Section on Surgery at the Thirty-Sixth Annual Meeting of the American Medical Association.

The operation was performed on the following day, as determined upon, the knife being first used, followed by stretching with the thumbs, and a thorough dilatation obtained, a half pint of hot water being thrown into the bowels every four hours during the day, and kept up for two days The patient expressed herself as greatly relieved after the operation, and enjoyed, for the first time for several nights, a refreshing sleep She was also placed upon hot milk diet with stale bread for a week, and the hot water douches continued every six hours for the same period At the end of eight days she was discharged cured I had an opportunity of seeing this lady quite frequently for many years subsequently, and enjoyed the satisfaction of knowing that my success in this case had been complete

Case 3—Four years ago I was consulted by a young lady twenty years of age, of delicate appearance, who informed me that she had been subject for six years to habitual constipation, with alternations of diarrhœa That two years before she had submitted to an operation for hæmorrhoids, from which she had suffered for more than a year previously, and experienced occasional losses of blood Although the hæmorrhoids had been removed, greatly to her disappointment she still had frequent hæmorrhages from the bowels, and at all times pain and discharges of large quantities of mucus, frequent attacks of diarrhœa, but generally constipated A careful examination of this case disclosed a contracted anus, sphincters firmly closed and resisting the introduction of the finger, no appearance or condition, however, indicating malignant disease, but presenting what I shall call a *rectismus* The lining membrane of the rectum was found thickened and villous, and exceedingly vascular, but not very sensitive beyond the sphincters External manipulation over the abdomen produced some pain along the descending colon This lady was required to go to bed and to commence at once the hot water douches, half pint every four hours, every alternate one containing two scruples of boracic acid and ten minims of tincture opii

On the third day after confining her to bed, I placed her under the effects of chloroform and operated by dilating the sphincters, entirely paralyzing, for the time, that muscle This was immediately followed by the application of nitric acid diluted one-half, to the inner surface of the rectum some distance beyond the sphincters The subsequent treatment consisted simply of the milk diet, hot douches with solution of boracic acid, anodynes for the first three nights, and internal administration of lime water, half an ounce three times a day in the milk At the expiration of two weeks she had so far recovered as to be able to leave her house, and experienced no difficulty or pain in the evacuation of the bowels This patient continued to enjoy entire freedom from any trouble, except more or less torpor of the bowels, for nearly two years, when I was again consulted for a return of the hæmorrhage of the rectum following defecation, and attended with pain An examination with the speculum showed the presence of three ragged ulcers about the size of a split pea, located just within the sphincter These were speedily destroyed, and the parts healed in a few days by three applications of pure nitric acid She has now been under my observation for eighteen months, and has had no return of the diarrhœa, or other evidence of intestinal disease

Case 4—In the latter part of May, 1883, an elderly lady, sixty years of age, the mother of several grown children, stout and healthy in appearance, consulted me for chronic intestinal catarrh, with which she reported she had been suffering for more than a year I saw her occasionally during the month of June, and directed her to use injections of hot water and be placed under a rigid system of diet, using but little medicine, as I was told that she had been pretty thoroughly medicated before consulting me About the 20th of June, she reported that she had suffered latterly with severe pains about the rectum during defecation, and at all times more or less uneasiness at that point This had been steadily increasing, and had finally become exceedingly distressing to her, and been attended with discharges of blood An exploration of the anus and rectum disclosed the presence of an oblong ulcer just within the margin of the anus, and extending for one inch up in the bowel, about one third of an inch wide and four or five lines deep, with smooth edges and base The surrounding tissues were soft and natural to the touch and in appearance, except the usual velvety feeling of the mucous membrane above the sphincter I was greatly relieved to find the condition of things that dispelled all apprehension of malignant disease, which I thought the clinical history of the case with the age of the patient, to some extent warranted The free application of nitric acid was made to the ulcer, hot water douches continued through the day, and a soft anodyne suppository at night was used Finding at the end of ten days that the use of caustics, anodynes and astringent lotions and suppositories, in conjunction with the foregoing treatment, had utterly failed, I resolved to divide the sphincters through the bottom of the ulcer, practice dilatation, and continue irrigation of the bowels with hot boracic acid lotion

On the 6th of July, assisted by Dr Acker, of this city, who administered chloroform, I made a partial division of the sphincter with a bistoury, and completed the dilatation by pressure with the two thumbs A large pledget of patent lint saturated with carbolized oil, was inserted and allowed to remain for eighteen hours The hæmorrhage was quite insignificant, but a large quantity of almost pure mucus was thrown off by the bowels A full anodyne was ordered for the night, and the patient put upon hot milk as a diet On the day following the lint was removed, and an application of an unguent, composed of sulphate of zinc, morphine and vaseline was made In this, as in all the foregoing cases operated upon, the bowels were kept inactive by the use of opiates for four days

This patient was left in charge of Dr Acker a few days after the operation, and not seen by me again for four weeks She continued, however, to use an abstemious diet, and to persist with the hot douche for some weeks On my return to the city she had so far improved as to be able to walk out without inconvenience, and suffered no pain in evacuating the bowels, had a good appetite, and pronounced herself as almost entirely cured She has since that date been under my observation, and seems perfectly well, having had no return of the diarrhœa, or other indications of her former disease

Case 5—In October last, I was requested to see a gentleman 52 years of age, a lawyer by profession, of sedentary pursuits during the last fifteen years of his life, regular and temperate in his habits He informed me that he had for several years, suffered from a slight bronchitis, attended with a troublesome cough, but no expectoration That eighteen months before, he began to experience some discomfort about the rectum after defecation, which had gone on increasing to actual pain, and that for the past six months there had been an occasional discharge of blood after evacuations of the bowels Contemporaneously with this feeling of malaise, he had been attacked with diarrhœa which had continued at intervals up to the time of his consulting me He had also undergone during this period a regular system of medication by two different physicians, who regarded his case as a simple catarrh of the large intestine, but that they had failed to afford him any permanent relief Upon making a careful examination of the rectum, I found a superficial fistula about one and one half inches deep, two small fissures at the anal orifice, and the lining membrane of the rectum congested and thickened A laxative of sulphur and Rochelle salts was administered, and instructions given that he should use hot water douches every four hours daily I explained the necessity to him of operating for the fistula, with the probability of an additional operation for dilating the sphincters He determined to try for a week the plan of irrigating with hot water alone, and abandon all internal remedies At the end of ten days I received a note requesting me to call and see him He had experienced much relief from the hot douches during the intervals of intestinal quiet, but at each evacuation the same pain was produced, his diarrhœa also had continued to recur, and he had finally concluded to submit to any plan of treatment which I might determine to pursue

On the day following, assisted by Dr Acker, who administered a mixture of chloroform and ether, the anæsthetic I usually prefer, I first divided the superficial fistula which extended just within the margin of the anus and dilated freely and forcibly the sphincters with the thumbs, packing the rectum for a few inches with a tent made of fine old linen, and well lubricated with vaseline An opiate was directed to be given four hours after the effects of the ether had worn off The next day I removed the pledget of linen and used the hot douche, repeating the opiate at night and directing a very light diet On the third day a laxative was given, which operated without occasioning much pain No further treatment was praticed in this case than the continued use of the hot water irrigation and a moderate diet At the end of eight days he was sufficiently well to resume his ordinary vocations, and pass from under my observation till the following January, when I met him on the street and received the gratifying intelligence that he had increased ten pounds in weight, and had experienced no return whatever or any symptom of his old trouble

Recognizing the important part played as etiological factors in the production of this disease by the muscular adjuncts of the rectum, and as one of the chief obstacles to be encountered in accomplishing its cure, it is important that we should bear in mind the anatomical relations of this organ to those muscles The extensive attachments of the levatores ani with its fibres converging to a central raphe encircling the bowel, and exercising a controlling power over its various motions, its contractions and its dilatations, and to a certain extent diminishing or increasing thereby the vascular supply of its coats, the external and internal sphincters presiding to a large extent over the act of defecation, maintaining under certain conditions by a tonic or spasmodic contraction of their muscular fibres, an abnormal blood supply to the bowel above, resulting in proliferation of tissue and necrotic areas of mucous membrane, the rich supply of nerves and blood vessels, and especially the particular distribution of rectal veins, constitute a vast field for investigation by the pathologist as well as an interesting and useful subject for observation and instruction to the general practioner

URETHRAL CALCULI[1]

BY JOSEPH RANSOHOFF, M D, F R C S, Eng,

PROFESSOR OF DESCRIPTIVE ANATOMY AND CLINICAL SURGERY
IN THE MEDICAL COLLEGE OF OHIO

The clinical pictures presented by foreign bodies in the male urethra are so varied that every case is likely to display special features of interest which will vary according to the form, seat of lodgment, and source of the foreign body In most cases this is a calculus which has descended from the bladder or kidneys, or in rarer cases, such as prostatic disease or stricture, has developed in loco In the vast majority of cases, the stone is single In the following case, for the "previous history" of which I am indebted to Dr J A Brown, of Germantown, two stones were found, which varied as much in size as in the symptoms to which they gave rise

J L, æt 37, farmer, had always enjoyed good health until sixteen years ago, when he suddenly suffered from severe pain in the urethra, associated with hæmorrhage and retention of urine, for the relief of which the catheter was used After continuing for a few weeks these symptoms subsided, and the patient

---

[1] Read before the Ohio State Medical Society June 4 1885

[illegible] to return to his work Since this attack he has always been in good health except on four or five occasions when a condition such as that just described recurred In the middle of January a similar attack supervened, for the relief of which the patient himself resorted to a soft catheter Only because febrile complications and rigors manifested themselves was Dr Brown sent for He recognized a swelling of the size of an orange just behind the peno scrotal angle, and when he introduced a silver catheter into the urethra a calculus was distinctly recognized All efforts to cause the expulsion of the foreign body were futile, attempts to extract it were equally unsuccessful It was therefore pushed backwards towards the bladder

I saw the patient for the first time on the 11th of February His temperature in the evening was 104°, and his pulse 122 He suffered excruciating pain, and could only urinate by means of the smallest Nélaton catheter Behind the peno scrotal angle the tumor already mentioned was recognized Notwithstanding its tenseness, a deep fluctuation was discernible This was unquestionably a peri urethral abscess, the result of an impacted calculus It impeded the passage of a solid instrument, and if opened, a thorough exploration of the urethra and bladder would be possible A free incision was therefore made and a half teacupful of matter evacuated A large sound could at once be passed into the deeper portion of the urethra where, just beyond the triangular ligament, it encountered an obstacle which imparted the peculiar grating sensation produced by contact with a calculus With the finger in the rectum a hard body of the size of a walnut could be felt underneath the anterior wall, just within the anus When this was pressed upon from within it formed a distinct prominence in the perineum Above the prominence made by the stone the prostate could be felt of normal size and consistence

After the abscess was opened, the febrile symptoms subsided so rapidly that on the 18th of February the stone could be removed I chose for this purpose the median operation Although this case was admirably suited for cutting in the gripe, I preferred the use of the lithotomy staff When the membranous portion of the urethra was opened the two calculi, which I beg to present, were removed The larger stone, weighing 265 grains, presents a smooth, rounded surface, is somewhat egg shaped, and measures 1¼ inches in length by 1 inch in width and thickness On section, it presents a central cavity and a large number of concentric rings According to Prof Fennel it is composed principally of the phosphate of lime, traces of the oxalate of lime and phosphate of magnesium being likewise present The second stone is very much smaller It weighs but 5 grains, and presents a very uneven surface From its appearance, it evidently resulted from the confluence of four or five smaller stones Although the bladder was carefully examined through the perineal wound, no other calculus was found On the second day after the operation, the patient passed his urine per *vias naturales*, and he progressed rapidly and uninterruptedly toward convalescence

The case which I have taken the liberty to report presents certain features of interest A glance at the two calculi will show that it was almost impossible for the large stone to have become impacted at the site of the abscess which was opened a week before the formal operation It is likewise evident that the smaller and more roughened stone was solely responsible for the severe symptoms detailed in the clinical history Just how long the larger calculus had been retained in the membranous portion of the urethra cannot be determined According to Dr Brown and a distinguished surgeon of Dayton, it was found in the bladder two years before the final operation If this be accepted, it developed with marvelous rapidity, since a stone of half its dimensions could hardly have been passed through the prostatic portion of the urethra Nevertheless even very large calculi are occasionally expelled from the bladder Thus, J S Dunning (JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 21, 1885) reports the case of a man 62 years of age in whom a stone as large as a hickory nut was expelled from the bladder and lodged behind the glans Urinary fistulæ developed behind the stone, which was removed seven months after its impaction When crushed it weighed 300 grains On the other hand it seems more probable that the larger calculus presented to day was lodged in the membranous portion for a considerable number of years, gradually receiving new deposits Indeed there is no limit to the time during which a stone may remain in the urethra without producing severe symptoms Fleury (*Bull de la Soc de Chir*, vii, 631) reports a case of urethral calculus, in the spongy portion, of twenty years' growth He had detected the stone fifteen years before the operation, which was rendered imperative by retention of urine In 1862, Mr Haynes Walton presented a stone to the Pathological Society of London It was removed from the perineum of a man who had probably carried it for fifty years without suffering greatly from its presence It finally produced retention and extravasation of urine, but its removal failed to save the life of the patient It measured 2¼ inches by 1 inch (Trans Path Soc, Vol xiii, 1862) From the specimen presented and the cases briefly referred to it will be seen that urethral calculi sometimes assume enormous proportions, either by dilatation of the urethra or the formation of a diverticulum Voillemier saw one the size of a hen's egg In the *Indian Medical Gazette* for 1883 (JOURNAL AMERICAN MEDICAL ASSOCIATION, 1883, p 145) is reported the case of a calculus lodged at the peno scrotal angle, forming a tumor as large as an orange It weighed 980 grains In 1878 R Parker removed a prostatic calculus weighing 1⅝ ounces by rectal incision A second but smaller calculus was found In this case a slight recto urethral fistula remained (*British Medical Journal*, 1878, Vol i, p 85

The case presented likewise impresses the fact that urethral calculi are not infrequently multiple, being associated with one or more stones in either the urethra or bladder Civiale reports the case of a man from whom 220 calculi were extracted from a pouch in the perineum In the museum of St Bartholomew Hospital is a part of 149 calculi taken from the middle of the spongy portion of the urethra

It is particularly in children that urethral calculi present certain features of interest, since in them the thin impaction is often followed by retention and infiltration of urine When these conditions exist, the usual causes of retention in adults, stricture and prostatic enlargement, can be excluded, and only trauma or impaction of a calculus remain as exciting causes Of 14 cases of impacted urethral calculus collected by Gault in 1862, only 3 occurred in adults Of the 11 which occurred in children, 8 were under 5 years of age, and in only one of the 11 cases was the stone lodged in the pendulous portion of the urethra, where it could be removed with the forceps In the other 10 it was impacted in the perineum, and in 5 of these urinary infiltration was present In these 10 the stone was removed by section, and in two of the cases in which infiltration existed, death followed

The treatment of urethral calculi presents but few points worthy of discussion, since it is evident that their extraction is always indicated When they are situated in the anterior portion of the urethra, where they can be reached with forceps or scoop, they are to be removed by either of these methods It should be remembered, however, that extensive manipulation is fraught with danger, since the impaction of a calculus in the urethra and efforts to remove it have been followed by the development of stricture (Sir E Home) Although the crushing of urethral calculi was already described by Albucasis as a formal operation, it has never, for obvious reasons, been generally adopted by surgeons The dangers attending it are considered of sufficient gravity to exclude it from recognized methods of treatment except in stones that are very friable When the stone is small and situated in the deeper portion of the urethra, it can often, by means of a large steel sound, be returned to the bladder, whence it should at once be removed by litholopaxy By far the safest method of treating urethral calculi is that by urethrotomy, and it should be resorted to as soon as the simpler methods already alluded to have been tried without success The dangers of the operation *per se* are scarcely worth considering, since important parts are not divided The only unpleasant consequences that occasionally follow it are urinary infiltration and fistula Neither of these complications is to be feared, however, if the operation be made early, and if the precaution be taken to use the catheter at regular intervals during the first three or four days following it

GEOGRAPHICAL PATHOLOGY OF CONSUMPTION[1]

BY G W McCASKEY, A M , M D ,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST, FT WAYNE COLLEGE OF MEDICINE FT WAYNE IND

II

Hygrometric Conditions —The relative humidity of the atmosphere has been regarded as an important factor in relation to phthisis It would seem, indeed, that the degree of saturation of the air with moisture must have a very decided influence upon the progress of pulmonary tuberculosis In accordance, therefore, with the plan outlined in the first paper, its bearing upon the prevalence of consumption will be studied in a very general manner

The annual rainfall has been taken as a standard in estimating the comparative humidity of different regions This standard has been adopted, notwithstanding the well known fact that it is not always correct, the effect of a large rainfall being modified by the porosity and drainage of the soil, and perhaps other conditions A large annual rainfall is so constantly associated with a high degree of humidity, however, and *vice versa*, that it will serve perfectly well as a basis of comparison The exceptions are too few to materially modify the result

We find, as we pass southward along the Atlantic coast, that the annual rainfall steadily increases until it becomes in Florida about double that of Maine Inversely the death-rate from consumption just as steadily decreases, until in Florida it becomes (in 1880) precisely one-half that of Maine But these facts, which seem so conclusive, are opposed by others of scarcely less importance For example, the region comprising New Mexico, Arizona, Colorado, Utah, Nevada, and Wyoming has an annual rainfall of from eight to sixteen inches—the lowest of any part of the United States The mortality from consumption for the entire group is also lower than for any state or territory not included in it This low consumptive death rate is not due to the general healthfulness of the region, but is rather in spite of the fact that the death rate from all causes is greater than the average for the United States

Again, in the region comprising Kansas, Nebraska, Iowa, Wisconsin and Minnesota, the annual rainfall is nearly three times as great as in the last named region The death rate from consumption is also nearly twice as great And this, notwithstanding the fact that the death rate from all causes is 2 6 per thousand less In other words, the hazard of dying of consumption is twice as great, although the general risk is about 16 per cent less

In the interior counties of Oregon the rainfall is 12 to 20 inches, and the deaths from consumption are 9 6 per cent of all deaths The coast counties have an annual rainfall of 50 to 70 inches, and the deaths from consumption are 12 8 per cent of all deaths In Washington Territory the interior counties have an annual rainfall of 12 to 16 inches, 12 6 per cent of all deaths are due to consumption The coast counties have a rainfall of 44 to 80 inches, 13 7 per cent of all deaths are due to consumption In southern California the annual rainfall is 12 to 16 inches, consumption is very rare In the infected region north of San Francisco the rainfall is 20 to 36 inches

Clearly, no constant relation can be traced between certain hyetal conditions and the death-rate from consumption, for, aside from minor discrepancies, which could easily be multiplied, in the two regions where it is less than in any other part of the United States, viz the Gulf States and the Colorado region above referred to, the annual rainfall is respectively the greatest and the least—being as high as eighty inches in the former, and as low as eight inches in the latter If any general law can be formulated regarding the influence of certain hygrometric conditions upon the progress of consumption, it can only be done while keeping in view the associated temperature These two factors cannot, of course, be entirely separated When considered together it will be found that, in the United States, a low temperature and a considerable degree of humidity is uniformly unfavorable We do not have to look far for an explanation of this fact A damp, cold atmosphere, which would be the necessary result, is the one above all others most likely to induce lowered vitality and internal congestions Such a combination is found in New England, and with what result all are familiar These internal congestions will always occur by preference in tissues where, as in tubercular deposits, the blood vessels are either obstructed or obliterated Every such disturbance will hasten the pathological process, hitherto slumbering, perhaps, in comparative quiet Its activity may continue or rapidly increase long after the cause has ceased to act And thus it is a matter of too common observation that a patient who might otherwise have lived in a fair state of health for years, or perhaps recovered, sinks rapidly into the grave

With a higher temperature the degree of moisture would seem to be of less importance Jaccoud says that the desirable limits are to be found between 70 and 80 hygrometric degrees, which is certainly a rather moist atmosphere With a higher temperature, he says, the dryness of the atmosphere promotes irritation of the respiratory mucous membrane, which is increased by the concentration of the normal and pathological liquids, induced by the rapid evaporation from the surface So far as mild or warm climates are concerned there seems to be no statistical or rational support for the view that dryness of the atmosphere is a *sine qua non* or even at all desirable for consumptives, or that moisture tends to promote the development of the disease

The question of soil moisture ought to be considered apart from atmospheric conditions This would, of course, be impracticable over large areas Dr Buchanan's investigations seem to show that thorough drainage lessens the mortality from phthisis In the table to which I have access, no reference is made to temperature or humidity, a serious omission in the study of a limited area The tables, moreover, show that along with the lessened death rate from consumption there was also a diminished death rate from most diseases—notably of typhoid fever and ague This result certainly ought not to have been, as Dr Andrews (Lumleian Lectures, *Lancet*, 1884) says it was unexpected at that time There is certainly reason for believing that the lessened mortality from consumption, as well as the like result in typhoid fever, diarrhœa, etc , was in large part if not entirely due to the improved sanitary conditions implied by thorough drainage of surface water Unsanitary influences are doubtless quite as potent for harm in phthisis as in other diseases In Salisbury, for example, the reduction in phthisis mortality was 49 per cent , while the reduction in typhoid fever mortality was 75 per cent , and of mortality from diarrhœa 60 per cent With a single exception (Rugby) the decrease in the mortality from phthisis, after drainage, was exceeded by the decrease in the mortality from either typhoid fever or diarrhœa, which shows that dampness of soil has more influence upon these diseases than upon phthisis

It is easy to anticipate the probable effect of dampness of soil upon the debilitated subject of a caco plastic deposit like tubercle The removal of this condition by drainage might render the prolonged existence of many patients possible, who would have succumbed but for this improved condition This is all explainable without assuming a special relation between phthisis and soil moisture, farther than is implied in the general unhygienic influence of the latter condition

Coast Influences —It has been asserted by Dr Flint and others that consumption is more prevalent upon the sea coast than inland In Maine this statement is correct, the coast counties having a much larger consumption mortality than the inland counties New Jersey has also a higher death rate than Pennsylvania, and Virginia than West Virginia On the Pacific coast the same relations also obtain between the consumption mortality of the coast and inland counties of Oregon and Washington Territories Returning to the Atlantic coast, we find that below Virginia the coast States have a much lower death rate from consumption than any of the interior States adjoining them These States have, in fact, collectively and individually a lower death rate from consumption than any other State east of the Mississippi river, except Wisconsin

A notable exception to the general immunity from consumption of the South Atlantic and Gulf Coast States occurs in Southern Louisiana, where 25 per cent of all deaths are due to this disease, as against 7 2 per cent in the northern, or inland, portion of the State This disparity must be due to some local conditions independent of proximity to the Gulf Coast, and can not weigh, unless it be as an exception to the rule, against the facts obtained from the extensive coast line above this region The percentage of deaths from consumption to all deaths in the interior or northern portion of the State bears a very close resemblance to that of the remaining Gulf and South Atlantic States, thus showing that the southern portion, where the mortality from this disease is more than tripled, is anomalous, and subjected to exceptional influences In the very next State, Texas, the mortality percentages are reversed, being 10 per cent for the coast, and 11 1 per cent for the interior counties

In California, the section just north of San Francisco Bay is one of the worst infected districts in the county, while Southern California is so free from consumption that it is resorted to by victims of the disease in the hope of benefit or cure Yet both are coast regions, kissed by breezes from the same ocean There are no available data at hand for mak ing a calculation of the percentages for these two sections of California. It is rather suggestive to note that on both the Atlantic and Pacific coasts the region of greatest immunity from phthisis is south, with its higher temperature, and the region of its greatest prevalence, north, with its lower temperature. The moisture laden air from the sea would have a very different effect, according as it was associated with a high or low temperature, in accordance with the views already expressed. It is possible that this may, in part, account for the varying mortalities from consumption found on different parts of the same coast line. This explanation seems entirely adequate so far as the main facts regarding the Atlantic coast are concerned, but may appear insufficient to account for the facts in California. It will be remembered, however, that this State has a very extensive coast-line. The mean annual temperature of San Francisco is five degrees lower than that of San Diego, a range including less than two thirds of the State. This difference is great enough to have a marked influence, though of course not great enough to account for the difference in mortality from consumption, which is very wide.

But whether this view be at all correct or not, the facts cited are certainly sufficient to warrant the assertion that consumption is not, with anything like uniformity, more prevalent on the sea coast than inland.

CHRONIC NECROSIS OF FIBULA AND TIBIA, OF TEN YEARS DURATION, AMPUTATION AT LOWER THIRD OF FEMUR, RE-AMPUTATION AT UPPER THIRD, RECOVERY.

BY R. H. JENKINS, M. D.,

OF HOGANSVILLE, GA.

The following case is deemed worthy to be placed on record on account of its interest from a surgical point of view, and also on account of its rather unusual course and termination.

Fred W., colored, æt. 15, parents had never had syphilis or struma. He was considered a healthy child until his fifth year, when there was a simple fracture of the tibia of the right leg at the middle third, caused by falling out of bed, two or three months after union the limb began to swell, the bone enlarged, and continued to enlarge for two years without suppuration, then two large ulcers formed, on the internal and external surfaces of the leg. From one, two small spiculæ of bone were discharged at different periods up to the date of my first visit.

His condition at that time was hectic, he was suffering with an acute attack of bronchitis, which yielded to treatment in a week, had very little appetite, and weighed only sixty pounds having shown no physical development whatever for eight years past, upon the surface of the leg, from the knee to the ankle-joint, there were nineteen ulcers, situated over the cloacæ that are to be seen in the shaft of the tibia, connected by numerous sinuses, the ulcers measuring in circumference from the size of a silver five cent piece to that of a silver dollar, all discharging an exceedingly fetid, ichorous, semifluid, dark-colored pus. From the commencement of suppuration he had not been able to extend the leg from the knee, or to bear any downward pressure upon the foot, owing to the continued rigid contraction of the muscles, which had drawn the leg at the knee backwards at a right angle with the thigh, and any effort at forcible extension made by himself, or a manipulator, brought on a violent rigor lasting from ten to twenty minutes, during which he complained of severe lancinating pains, commencing in the foot, and extending up the entire leg, terminating at the lower portion of the back, his skin would be bathed in a profuse and general perspiration all over the body, with the single exception of the diseased portion of the leg from the knee to the toes. The pains would then suddenly cease and the sensations of cold and numbness, which he had felt in the leg for three or four years, would return, and continue until another attempt at extension was made. I ordered cod liver oil, iron and quinine, which caused a general and rapid improvement.

On August 20, 1883, twenty days subsequent to my first visit to him, assisted by Drs. Cook and Hudson, I commenced amputating at the lower third of femur, through normal skin, tissue, muscles and periostium, until I came to the medullary canal, which was half filled with a pinkish colored, grumous matter in a degenerating state, and detached from the periphery of the bone. The fibula represents the condition of the femur, minus the medullary substance, from the middle third to the knee, except the condyles, tuberosities and articular faces. The patella and all the bones of the foot were free from disease. The shaft of the tibia had a small sequestrum encased in new bone, and in the latter are to be seen the numerous cloacæ, while the articular surfaces for condyles of femur, inner and outer condyles, internal malleolus, and lower extremity of the reproduced bone had undergone necrosis. The medullary canal of the fibula was in the same condition as in the lower extremity of femur. The head of the bone, and external malleolus had undergone complete degeneration and had been discharged. The shaft had been fractured by muscular contraction, and showed commencing necrosis in its periphery.

I immediately re amputated at the upper third of the femur, through normal bone, and used carbolized water dressings to the wound, which healed by first intention. I continued the supporting treatment as above described for one month after the operation. Six months afterwards he came to my office with a sound stump, and weighed one hundred and forty pounds. I saw him again in 1885, eighteen months after the amputation, his health was good, and he was self supporting by harness making. The most remarkable features in this case were the extraordinary powers of resistance to septicæmia and constant drainage prior to the removal of the diseased member, and the subsequent continued and complete recuperative capacity of the system, under the most unfavorable hygeinic conditions.

MEDICAL PROGRESS

SURGERY

Treatment of Spina Bifida by the Injection of Iodo-Glycerine Solution —The Clinical Society of London, some time since, appointed a committee to consider this subject, and they made their report at the meeting held May 22, 1885, an abstract of which may be found in the English journals The committee undertook an examination of all the specimens of this deformity contained in the London museums, as well as those in Cambridge and Glasgow, and sundry others placed at their disposal by different contributors to the report The subject was therefore divided into two parts *first*, the pathological anatomy of spina bifida, and *secondly*, the treatment of the deformity

Pathological Anatomy The term spina bifida was used to define certain congenital malformations of the vertebral canal with protrusion of some of its contents in the form of a fluid tumor With very rare exceptions, the malformation affected the neural arches of the vertebræ, and the tumor projected posteriorly, in rare cases, however, the bodies of the vertebræ were involved, the tumor in such cases protruding anteriorly into the thorax, abdomen, or pelvis between the lateral halves of the bodies affected The specimens fell under three chief divisions 1, protrusion of membranes only (spinal meningocele), 2, protrusion of membranes together with the spinal cord, and its appertaining nerves (meningo myelocele), and 3, protrusion of membranes together with the spinal cord, the central canal of which was so dilated as to form the sac-cavity, the innermost lining being constituted by the expanded and atrophied substance of the cord (syringo-myelocele) The comparative frequency of these three varieties is meningo myelocele, meningocele and syringo-myelocele last The dissection of a typical case was given in the report, with the theory, best explaining the pathological anatomy, which assumed a primary defect of development of the mesoblast from which the structures closing in the vertebral furrow were developed

Clinical Course and Treatment of Spina Bifida The Registrar General's Report for 1882 showed 649 deaths from spina bifida in England and Wales, of which 612 died under one year of age The committee held that, though a certain number of these deaths were due to local causes—rupture of the sac, draining away of the cerebro-spinal fluid, and subsequent septic meningitis—yet in a large proportion of the cases death ensued from the marasmus and general defective nutrition so frequently associated with the deformity which could not be remedied by any local or other treatment As regards treatment, injections with simple solutions of iodine showed a considerable amount of success Good results seemed to have been obtained from ligature of the sac Excision likewise had a considerable proportion of success The plan of repeated tapping and pressure gave the least successful results of any The injection of Morton's fluid showed a percentage success of between 50 and 60 The high mortality was thought to be largely due to the treatment having been adopted in unsuitable cases on account of its simplicity and supposed safety In spite of the favorable results of ligature and excision, the committee reported against these methods of treatment, and advocated the plan of treatment by injection, and preferably by the injection of Morton's fluid

Prof Humphrey, of Cambridge, in a lecture on this subject (*Edinburgh Med Jour*, June, 1885), considers the sac as most likely developed from a subarachnoid lymph space In the treatment by injection, he thinks it better to introduce the needle, not in the mesial line, especially in the upper part, where the cord is almost certain to be connected with the walls of the sac, but on one side Further, the separateness of the cavity of the sac from the cavity of the spinal arachnoid, in most instances, is some security against the direct passage of the injected fluid into the latter cavity, and the advantages of Morton's fluid, as an injection, probably depend upon the addition of glycerine to the iodine and iodide of potassium, lessening the liability to the diffusion of those irritating substances through the delicate lining of the sac into the surrounding subarachnoid tissue

Cocainisation of the Bladder —Dr P Bruns, of Tubingen, records (*Berl Klin Woch*, No 21,) a case of litholopaxy in which the bladder and urethra had been rendered insensitive by cocaine The patient had suffered from symptoms of stone for four years, and, on sounding, the stone was found to be hard and rough, and two centimetres and a half in diameter There was also considerable purulent cystitis As a preliminary measure the bladder was washed out with boro salicylate solution, then twenty grammes of a two per cent solution of cocaine were injected into the bladder, and ten grammes into the urethra By shifting the position of the patient the contact of the injection with all sides of the bladder was ensured After a few minutes' interval the bladder was filled with the boro salicylate solution, and the operation proceeded with Owing to the hardness of the calculus thirty-three crushings were necessary, occupying twenty-two minutes, but during the whole period no pain was felt, although previously the patient had hardly borne the passage of a catheter During the evacuation pain was experienced each time the bladder was distended, but the anæsthesia had lasted for half an hour Finally, a small quantity of a ten per cent iodoform glycerine solution was injected, with a view of protecting the abraded bladder from purulent absorption The calculus, which was of the oxalate mulberry variety, weighed 4 grammes A speedy recovery ensued —*Lancet*, May 30, 1885

Cocaine in the Extraction of a Needle from the Foot —Mr Samuel Nall reports a case in the *British Medical Journal*, of June 27, in which a fragment of a needle, lying about a quarter of an inch beneath the surface of the foot, was easily and painlessly extracted after the application of a 4 per cent solution of cocaine

SATURDAY, JULY 18, 1885

THE INTERNATIONAL MEDICAL CONGRESS OF 1887

The events of the past week have only served to demonstrate more clearly the appropriateness of our remarks in the JOURNAL of last week concerning the inexcusably hasty action of several prominent members of the profession in Philadelphia, Baltimore, and Boston, regarding the action of the Committee on the Organization of the International Medical Congress of 1887, at its recent session in this city Such action was taken, not only before the proper officers of the Committee had made any authorized report, but before the Committee had in any proper sense so far completed their work as to make a publication of the same proper The very nature of the work the Committee had to do, with the limited time allowed for the meeting, rendered it highly important that their action should be carefully written out and reviewed at least by the Executive Committee, the prominent appointees conferred with, and time given to receive suggestions, supply defects and fill vacancies caused by declinations or otherwise

The General Committee as first organized had its first and only meeting in Washington in November, 1884, and they took four months subsequently in which to confer and further perfect their work through the agency of their Executive Committee, before publishing the results, and then left several parts incomplete But now, forsooth, in four days after adjournment of the Committee, on mere partial, verbal reports, a few grave, learned, and hitherto justly honored members of the profession in the three cities named, hasten together and denounce the work of the Committee as "detrimental to the interests of the medical profession in America," and ostentatiously resolve to "decline to hold any office in said Congress as now organized" If these men had first taken pains to learn accurately what the present Committee had done, and then assembled for the purpose of considering the more important items with a view of suggesting improvements and thereby aiding the Committee in rendering their work more complete and acceptable, they would have given evidence that they had more regard for the honor and interests of the profession than for their own personal prejudices and dislikes, in other words, they would have acted like *men* and not like half grown school boys Although the assembly of twenty-eight in Philadelphia, the nineteen in Boston and the twelve in Baltimore each solemly adopt preambles and resolutions, not one of them specifies any particular provisions or rules that had been adopted by the Committee on Organization, the practical working of which would prove "detrimental to the profession in America," or in any other country But from the editorial comments in the *Medical News* of Philadelphia, the inference may be drawn that the alterations made in the first *Rule*, by which the American membership of the Congress was limited to delegates appointed by the American Medical Association and the State and local societies in affiliation with it, was the chief cause of dissatisfaction

It is claimed that the International Medical Congress is a purely scientific body, having no reference to particular national or State medical organizations Evidently recognizing some force in this claim, the members of the Council of the New York State Medical Association held a meeting, not like their brethren in Philadelphia and Boston, to denounce the work of the Committee and hasten to wash their hands of all further responsibility, but to devise, if possible, some improvements And after due deliberation, they make to the Committee on Organization the following suggestion

"*Resolved*, That the Council of the New York State Medical Association respectfully recommends to the Committee of Arrangements for the International Medical Congress the following modification of the rule by which the American membership of the Congress is to be constituted, to wit

"That the American membership of the Congress be constituted of delegates, who shall be entitled to participate in the business and scientific proceedings, and of members who shall be entitled to participate only in the scientific proceedings of the Congress, that the delegates may be appointed by the American Medical Association and by State and local organizations in affiliation therewith, in the proportion of one delegate for every ten or fraction of ten members of the organizations thus represented, that members of the regular medical profession of the United States may become members of the Congress by registering their names as such and by taking out tickets of admission"

For all the purely *scientific* interests and proceedings of the proposed Congress, this proposition opens the door to all the members of the regular medical profession of the United States to become members of the Congress, by simply "registering their names as such and taking out tickets of admission"

This proposition will doubtless receive the favorable consideration of the Committee on Organization, and is certainly liberal enough to satisfy the purest scientists in this or other countries If we are correctly informed, there is another part of the work of the Committee that needs further attention During the session in Chicago, the Committee re-adopted Rule 6, without alteration, which reads as follows

"6 All addresses and papers, read either in the General Meeting or in the Sections, are to be immediately handed to the Secretaries The Executive Committee after the conclusion of the Congress, shall proceed with the publication of the transactions, and shall have full power to decide which papers shall be published, and whether in whole or in part"

The duties enjoined in this rule are very important, and the Executive Committee referred to was a Committee of the Congress provided for in the previous Rule 10 But the present Committee, in changing Rules 9 and 10 in such manner as to make the General Committee on Organization a simple Committee of Arrangements, with officers entirely separate from the officers of the Congress, have omitted to provide for any Executive Committee of the Congress proper This is an important omission, and we would suggest that the Committee supply it by a rule making the President of the Congress, the Secretary-General, the Chairmen of the Finance Committee, and the Chairman of the several Sections an Executive Committee of the Congress for the purposes named in the sixth rule These considerations make it desirable that the Committee have time for further conferences before any formal publication of their proceedings

We understand that the officers of the Committee are already taking the preliminary steps for another meeting early in September, and if the professed friends of the Congress will take half as much pains to aid the Committee in completing wise and satisfactory arrangements, as some of them do to find fault and throw obstacles in the way, there will be no trouble in securing good arrangements and a successful Congress

---

"A cardinal source of dissatisfaction with the new organization is that it is under the control of a handful of discontented men, who were not included in the preliminary organization, and who stirred up this trouble for what they could make out of it"—*Medical News*, July 11, 1885

Just so, the simple truth will come out sometimes even by accident After all the pretenses, then, about changes in the plan of organization, a *cardinal* source of the dissatisfaction with our learned friends of the Quaker City, is that poor Mordecai is found sitting at the King's gate

---

"There can be no question that the Committee of eight had full and specific authority to add to its membership, and that the original Committee thus enlarged was authorized to make all arrangements for the Congress, so far as the American Medical Association could give such authority, The International Medical Congress accepted the invitation with this understanding, and thereby practically accepted the original Committee of eight as its Committee of Organization"—*Medical News*

Grant it all, and there can be no possible question that the same American Medical Association from which the Committee of eight derived all the authority it ever had, made itself fully responsible for the acts of its Committee, and possessed just as "full and specific authority" to modify the powers conferred whenever it might choose to do so And yet on the first attempt to do this, five of the eight voluntarily abandon their position, and ingloriously turn their backs upon their duties both to the Association and the Congress Pure unselfish patriotism that!

THE OPERATIVE TREATMENT OF ASTHMA

Such is the title of an important and interesting paper read by Dr Wilhelm Hack at the Fourth Annual Congress of Internal Medicine held last April at Wiesbaden, Germany This address forms the latest contribution to our knowledge of certain reflex phenomena which have been carefully studied by French, German, English and American rhinoscopists We refer to certain neurosal conditions, notably hemicrania and asthma, which are found to be occasioned reflexly by diseased states of the nasal mucous membrane Attention was first directed to this possibility by Voltolini, who reported the cure of a case of asthma by the removal of a nasal polypus Similar observations were subsequently made, and the subject was discussed, by Hanisch, Frankel, Hack, Bresgen, Sommerbrodt, Porter, Daly, Todd, Spencer, Mulhall, Joal, Jacquin, Mackenzie, Eslberg and others in Europe and America. It was speedily discovered that not merely asthma and hemicrania, but also cough, supraorbital neuralgia, nightmare, chorea, epileptiform seizures, dizziness, palpitation of the heart, dyspeptic symptoms and other phenomena, attributable to vaso motor disturbance might in rare instances have their point of departure in structural alteration or abnormal irritability of the nasal cavities.

For the most part these conditions are such as partially or wholly occlude the nares, as polypi, but Hack's observations have shown that these reflex phenomena are not due necessarily to the polypi, that is, to any obstruction of the nasal orifice, but to irritability of the nasal tissues. In several instances he removed redundant and irritable portions of adjacent mucous membrane, leaving the obstructing new growths *in situ*, and thereby achieved an immediate cessation of the asthma. Clearly then, the obstruction was not the cause of the mischief. In accordance herewith, Schaffer announced that reflex manifestations might accompany chronic nasal catarrh, and endeavored to account for the asthmatic complications as being reflex through the vagus, and not at all due to direct impediment to the free passage of air through the nasal fossæ or to any chemical action of the polypi upon the inspired atmosphere, as was at first suggested.

Frankel went further than Schaffer and explained all reflex manifestations as dependent upon an abnormal irritability of the sensory nerves distributed to the mucous membrane of the nose. Hack accepts this theory as satisfactory in many cases, but believes in the majority of instances that the connecting link between diseased conditions of the nose and the reflex disturbances, accompanying them, is an acute or chronic turgescence of the turbinated bodies, particularly the anterior extremity of the lower turbinated body. Accordingly, he destroys these hypertrophied structures, with the galvano cautery, in every case where their enlargement seems to be the disturbing element. In his paper before the Congress, he reports two hundred and forty cases of hemicrania which were cured by the operative treatment. Of eighty seven cases of asthma, a large majority was entirely relieved. Space does not admit of a detailed account of some of his cases, and hence our readers are referred to the *Berliner Klinische Wochenschrift*, Nos. 21 and 22. Hack's statistics are so gratifying that it would be natural and excusable if young rhinoscopists were rendered wildly enthusiastic by the perusal of them, and should expect astonishing results to follow every operation for the removal of redundant tissue or new-growths within the nasal fossæ. Yet, Hack himself, out of a vast experience, deprecates, and warns against unbounded enthusiasm. While every rhinologist should be on the lookout for these cases, he must not be disappointed if he goes long without finding them.

Hack has undoubtedly explored this field of research the most thoroughly, and obtained the greatest fruits. Last year he published a monograph entitled "Concerning the Operative and Radical Treatment of Certain Forms of Migraine, Asthma, Hay-Fever and Numerous other Allied Conditions." As it is beyond the scope of this article to review this monograph, we will only make a few extracts from the author's conclusions. Among conditions which reflexly occasion a turgescence of the turbinated bodies, he mentions pathological changes in the mucous membrane of the nose, or pharynx, excitation of nerves of special sense and sensory cutaneous nerves, disturbances of the sexual organs, as *e. g.*, menstruation, direct irritation as from dust, heat and cold. On the other hand, turgescence of the turbinated bodies occasions various phenomena of a reflex nature. And in many of these Hack attributes the symptoms to a vaso dilator influence upon the vessels of the part. Thus for instance, he explains flushing of the upper part of the face, hyperæmia of the conjunctivæ, and in one case an amount of redness and swelling of the skin which actually amounted to œdematous infiltration of the part concerned. The headache, lachrymation and other symptoms belonging to acute coryza and hay-fever, he would also account for as reflex manifestations.

In conclusion of this highly interesting and important subject, we think a word of caution not out of place, and hence, quote the words of Morell Mackenzie. He says: "Whilst fully admitting that many reflex phenomena may arise from disease within the nose, I must caution the younger specialists that the various complaints, referred to as resulting from nasal disease, are much more frequently due to other conditions, and that every other possible cause must be eliminated before the nose is incriminated."

THE SURGICAL TREATMENT OF CYSTS OF THE PANCREAS.

Such is the title of a valuable paper read before the late annual meeting of the American Medical Association by Dr. N. Senn, of Milwaukee, and published in the July number of the *American Journal of the Medical Sciences*. It may be remarked, *en passant*, that as this paper was read before the As sociation, it was the property of that body, and as that body has an official organ for the publication of papers belonging to it, it does not need very much argument to show that the paper is out of place in any other journal until it has been published by the official organ, except by special permission of the Association

As the basis of his paper, Dr Senn reports a personal case of cyst of the pancreas in which he performed laparotomy, with the result that the patient recovered In this case there was a history of traumatism, a severe blow on the left side of the abdomen and back, subsequent diarrhœa, and the appearance of a tumor in the left hypochondriac region two weeks after the injury Five weeks after the receipt of the injury, he was admitted to the Milwaukee Hospital, and came under the care of the author of the paper At this time there was considerable emaciation, and the patient complained of a sensation of fulness and weight in the region of the stomach, always increased after eating, and only relieved by vomiting The tumor occupied almost the whole of the epigastric region and the entire left hypochondriac, the most prominent part being to the left of the median line, and about three inches below the ensiform cartilage There was a line of dulness extending from the left nipple to within an inch above the umbilicus, posteriorly the dulness extended from the eighth to the inferior border of the twelth rib There was distinct fluctuation on percussion, the wave of fluctuation being conveyed across the whole area of dulness The heart was so much displaced upwards that the apex beat was distinctly felt in the fourth intercostal space "The stomach was artificially distended by carbonic acid gas, when it was ascertained that it was pushed to the right and compressed by the tumor" In order to ascertain the nature of the contents of the tumor, the needle of a hypodermatic syringe, after being thoroughly disinfected, was introduced into the most prominent portion of the tumor, and some of the fluid withdrawn It was viscid, slightly opalescent, alkaline, and contained a considerable amount of albumen

The weight of evidence being in fayor of a cyst of the pancreas, laparotomy was performed under the *strictest antiseptic precautions*, and the cyst was opened and emptied, and its walls drawn forwards into the wound and stitched to the parietal peritoneum, this having been previously united with the skin The patient did not vomit after the operation, the pulse did not rise above 90, and the highest temperature was 100° F, on the day after the operation The sutures were removed at the end of the first week, no other dressings were applied, and the skin healed without suppuration, only a small amount of pus escaping through the fistulous opening with the secretion "The secretion became clearer after the operation and continued to discharge in varying quantities for almost four weeks One of the drainage tubes, inserted at the time of the operation, was removed at the first change of the dressing, and the second was gradually shortened and entirely removed four weeks after the operation At the end of the second week, the cyst was explored with a disinfected probe, which passed to the depth of eight inches in the direction of the tail of the pancreas" The fistulous tract, becoming lined with granulations, grew smaller and shorter, and at the end of eight weeks it was so narrow as only to admit a small probe, which passed to the depth of four inches In January, 1885, the patient was discharged cured, with the fistula completely closed, and perfect digestion

We have only commendation for the manner in which this case was treated Though there are several affections which may come up in the differential diagnosis of cystic disease of the pancreas (or of almost any abdominal tumor), the treatment for those which are most likely to be confounded is practically the same at the outset—exploratory aspiration or incision It is very unlikely that a surgeon could, after a thorough examination, with a knowledge of the history of the case, mistake an aneurism, malignant disease of abdominal organs, circumscribed peritonitis with exudation, or ascites even, for cystic disease, echinococcus, or hydro or pyo nephrosis And Dr Senn very pertinently says It may be stated that a positive diagnosis has so far not been made in a single instance (of cyst of the pancreas), and that for all practical purposes it is only essential to make a probable diagnosis between a pancreatic or some other kind of a cyst which would call for the same kind of surgical treatment In very obscure cases an exploratory incision under antiseptic precautions for diagnostic purposes is a justifiable procedure

Dr Senn recommends that the incision be made, not through the linea alba always, but through the most prominent part of the tumor, for if adhesions form they would naturally begin at this point, the incision over the most prominent part would increase the facilities for proper drainage, and the band of connective tissue, resulting from atrophy and obliteration of the cyst, would form a permanent ridge between the gland and the cicatrix in the abdominal wall, and this band should be where it will least interfere with underlying organs

SOCIETY PROCEEDINGS

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY, AND HYGIENE

Meeting of April 8, 1885

DR JAMES C WHITE IN THE CHAIR

DR F F DOGGETT read a paper entitled

METALLIC POISONING FROM CANNED FOODS, WITH A REPORT OF SIX CASES OF POISONING FROM CANNED TOMATOES

Considering the vast amount of canned food consumed and the chances of metallic poisoning in its use, it is certainly remarkable that so few cases of such poisoning are on record, hence the interest of the cases reported in this paper From a hasty search of the literature of the subject, drawing references from the five volumes of the *Index Medicus*, as well as other sources, but a comparatively few cases have been found Most of these have occurred in England and America, but few in France and Germany, this being probably due to the fact that much less canned food is used in the two latter-mentioned countries

In addition to the above, I have collected together certain hints about the process of canning foods and the appearances of bad cans and their contents, whereby, in cases of lead poisoning or irritant poisoning, if we suspect canned food as the cause, we may arrive at some opinion as to the suspected can and its contents, and this will be found to be a most practical help to us as practitioners

Dr Johnson, in a paper read before the New York Legal Society, April 8, 1884, gives an account of several cases of corrosive poisoning from zinc and tin chloride in canned goods The zinc chloride is with tin chloride formed into a flux or solution, and is used in soldering the ends and sides of the cans instead of rosin and ordinary solder, than which it is much more convenient though very poisonous, and in spite of great caution it may at times get into the contents of the can So certainly is this means of poisoning from canned food recognized that the State of Maryland has passed a law forbidding the use of the poisonous zinc and tin chloride amalgam in canning food

In all his cases diarrhœa was very marked at first, which is not usually the case in simple lead poisoning In the cases in which the pulse was especially examined there was great disturbance, it being irregular and very quick, from 120 to 150 In simple lead poisoning the pulse is slow, according to Flint According to Reeve, it is sometimes quickened But in poisoning from an irritant, metallic poisons as copper, zinc, or tin, the pulse is small, irregular and quick Stannous chloride is very poisonous, the symptoms from poisoning by this salt resemble corrosive sublimate poisoning, though much milder It is improbable that in these or similar cases of poisoning a poisonous tin salt could come from the wall of the can itself, though there is some reason to suppose that lead may so contaminate the contents of the can First in regard to tin

In 1878, A E Menke reports that in an analysis of many specimens of canned lobsters, apples, and pineapples he found tin present in the contents of all, and in the latter as much as 1 3 gr to lb This was reported in the *Chemical News* (England) In 1880, Hehner, in the *Analyst* (Eng), reports that he found tin present in canned asparagus, tomatoes, peaches, pineapples, cherries, corned beef (five brands), oysters, sardines, salmon, mutton, chicken, turkey and canned milk (three brands) In the milk there was one-tenth gr to lb In soup, one-half gr , and in oysters seven-tenths gr Later, Wynter Blyth, in a report to the Vestry of Marylebone, found in twenty three samples of tomatoes, in cranberries, apricots, and pineapples, larger quantities in in form of stannous hydrate, which is much less active than stannous chloride In some of the above specimens he found as much as 14 3 gr per lb , and the average amount in all examined was 6 2 gr per lb In some, even the juice had a metallic taste In some cans the tin was corroded By experiments on Guinea-pigs with stannous hydrate, Orfila found that it took 174 gm per kilo in weight of body of the animal to produce death Assuming man equally susceptible to the poison as the Guinea-pig, it would take from three to four drachms to kill a man It is probable, however, that small repeated doses act more powerfully, as with mercury Such a result is likely to follow after long continued living on an exclusive canned diet, as on long voyages Such a state of affairs was found to be present among the officers and crew of the ill fated Jeannette on their memorable retreat over the ice to the coast of Siberia The goods had been canned for two winters and two summers, and had been a constant article of diet The longer the vegetable and fatty acids are in contact with the metal the more will be the likelihood of a poisonous stannous compound forming In Germany Drs Unger and Bodlander examined a great number of cans of fruit and vegetables, and always found tin present in the solid parts as an insoluble stannous compound, the per cent of tin being 04

On May 5, 1884, Professor Attfield, of England, read a paper before the Pharmaceutical Society of London, detailing a large number of analyses of sixteen varieties of foods, in only a few cans of which could tin be found, even in small quantities In his opinion a harmful quantity would produce such a disagreeable taste as to render it unfit for food, further, that the "public has not the faintest cause of alarm respecting poisoning from either tin or lead in canned food," further, that when symptoms have been reported they have resulted from stannous or plumbic chloride, formed with hydrochloric acid in soldering, this tin salt being very poisonous He further thinks that a poisonous tin or lead salt may be formed by contact of the fatty or vegetable acids on the metal of the can or solder when kept open in the air waiting to be used A commissary officer, high in the United States Army, has made the statement that during a series of years in different parts of the country hundreds of thousands of cans of food have been used by the army, and no case of poisoning from such food has ever been reported That extraordinary care is used in selecting the cans in the United States service I know to be true, as a gentleman lately in the Navy informs me that all swelled cans are rejected

It is probable that a large part of the canned food at any time on hand has not been freshly canned Hence the great resistance made to the passage of the proposed bill through the New York Legislature in the spring of 1884 by the producers of canned goods The bill was to the effect that each can should be stamped with the date of its preparation I have found that in "the trade" the inferior goods are known as "Seconds" and "Re-processed," which means that the cans which have failed in the first preparation to become hermetically sealed, or those which have rusted or got punctured and the inside of the can oxidized and chemically acted on by the acids of the contents, and perhaps the contents partially decomposed, such cans are superheated in steam or boiling water, resoldered, and returned to the market So far as poisoning from tin is concerned by formation of a poisonous compound from chemical union of acids of the contents of the can with the metal, either in the solder or from the walls of the can, or from careless use of stannous chloride in soldering, the great bulk of testimony shows that such poisoning may occur The apparent discrepancy between Professor Attfield's testimony (although he admits poisoning may occur from tin) and other authorities is explained when we recall that they were examining different specimens

Four of his cases were cases of lead-poisoning from eating the canned tomatoes, and having demonstrated the presence of lead in a specimen of the same brand obtained from the same source, it remains to inquire how lead may get into the contents of the can When genuine solder is used some small quantity of lead in it may get in and be acted on by the contents, forming a soluble salt, and so be absorbed, but in all the analyses to which he has had access this has never been considered of consequence enough to suggest poisoning, except with a strong acid contents

The other possible source of the lead is important It appears than an amalgam of tin and lead is cheaper than the former metal alone, hence there is always an inferior quality of tin in the market which contains from ten to one per cent of lead, and such tin has been used in canning foods, and lead-poisoning from such a cause has resulted For instance, Dr Magruder publishes a case of lead-poisoning from eating canned corn He found that tartaric acid was used in preparing the corn, and that the tin of the can had a certain amount of lead as an amalgam with it This he proved by testing the tin of the can, and he found the same to be true in several cans of the like brand which he tested This was verified by Dr Onderdonk, of St James College, Maryland, who out of many cans tested found only two free from lead Dr Dorsh reports that out of a large number of cans tested he found lead as an alloy with tin in almost every case An alloy of lead and tin is more easily oxidized and dissolved than tin alone I have tested twenty cases of many brands, from the cheapest to the highest price, and have always found lead present in the tinning of the cans This, too, with weak solutions of nitric acid, allowing the acid to act some time and then getting the characteristic yellow iodide of lead by dropping on a crystal of potassic iodide The principal examiner of chemicals in the Patent Office at Washington says that all commercial tin is alloyed with lead, and that the formation of salts of lead and tin when in an alloy is especially liable to take place in presence of fruit acids Professor Wormley, of the University of Pennsylvania, gives his testimony that several cases of lead poisoning have occurred after eating canned fruit Naunin, in Ziemssen's Cyclopedia, says a mild lead-poisoning may occur from the action of fatty and vegetable acids on the lead in an alloy of tin and lead Some specimens, such as Bohemian tin, may contain ten per cent of lead

On the other hand, F P Hall, after analyzing a number of specimens of tin used in canning food, says the tin is generally pure, and in his opinion such acids as would be present in canned food would not affect impure tin enough to cause poisoning The French Commissioner of Hygiene admits cases of lead-poisoning from canned food in cans made of tin and lead alloy, and suggests that a law should be made in France compelling the use of pure tin M Gautier, in France, reports that no death has been traced to canned goods, but many cases of lead-poisoning have been reported from continued use of such goods To show how the specimens of tin used in canning goods may differ, so good an observer as Professor Remsen, examined some of the same brand of canned corn which produced lead-poisoning in Dr Magruder's case, and reports that lead was absent in the corn, also in the metal of the can So that, as pointed out in reference to poisoning from a salt of tin, contradictory evidence of this kind should have no great weight, as some specimens of the same brand are good and some bad In the case of lead poisoning seen by the writer, it seems most probable that the lead salt absorbed was produced in the cans by the chemical action of a vegetable acid from the tomatoes acting on the lead contained in the alloy of the can, and possibly on a little solder which may have got in through carelessness The writer regrets that he did not test the suspected can for lead in form of an alloy

In general, the possible sources of danger to the consumer of canned foods are to be found in the structure of the can, the solder, or in the contents, *per se* As to poisoning from decomposed animal canned food, many cases have been reported For instance, in the *British Medical Journal* of November 1, 1879, there is reported the account of the poisoning of twenty-one persons from eating "Chicago corned beef" The symptoms were those of an irritant poison, even proceeding to collapse, though all the cases recovered Usually the unpalatableness of the contents is enough to warn the consumer not to partake The bad condition of the contents can often be foretold before opening the can; as, if air has been admitted at the time of soldering, or from improper methods of preparation, or original unsound contents, decomposition will take place and fermented gases be formed within the can, together with the acids; this will cause the ends of the can to bulge outward. In "the trade" such cans are called "swells." Such cans should be rejected. A recent writer on the subject has said that a bad can will have a rattling contents on being shaken. I think this proves nothing as to the badness of a can; for, in case of between thirty and forty cans of tomatoes, the contents were found perfectly good on eating, though before opening the contents of the cans rattled on shaking.

Among the cheaper grades of canned tomatoes I have occasionally found that the contents will curdle milk, though it may taste and look as usual. I think in such cases that some fermentation has taken place, and in the process a vegetable acid has been found to curdle the casein of the milk. Ordinarily, the juice of the tomatoes mixes with the milk without curdling it. Accordingly, if a little of the juice of a suspected can of tomatoes will curdle an equal quantity of sweet milk, one would be justified in assuming the presence of some vegetable acid in the tomatoes. It is only a question of amount of acid and length of time it remains in contact with the surface of the can that will determine the presence of a lead salt in the contents of the can. The contents may have a metallic or astringent taste, as in the above-reported cases, and then it should be rejected. As to the solder, there is danger of corrosive poisoning from presence of tin, or zinc, or lead, or all. For it is now, or has been, a custom, within a short time, to use a flux of tin and zinc chlorides, and with hydrochloric acid to solder on the head of the can. This is so poisonous that a small quantity in the can would do much damage. The ordinary way of soldering is with a solder of tin and lead with rosin, which last in melting leaves its trace around the head and at the side of the can. Hence, reject a can not showing this, as then the presumption is that the poisonous solder has been used. A small piece of the tin and lead solder may fall into the can, but as yet has never been shown to have done harm. However, if a large surface of solder is left on the inside of the can by the solderer, and if acids were formed in the can, there would be a good chance for lead salts to be formed; for ordinary plumber's solder contains seventy five per cent. of lead—a much larger amount than would be found in the turning of the can.

The acids likely to be formed by fermentation or decomposition of the contents of the can are from vegetables and fruits, acetic acid, malic, citric, and tartaric; from meats or fish mostly butyric acid.

As solder is somewhat expensive in quantities, and an unskilful solderer will use more than a skilful one, solder in sticks is sold to each man. We may see from this that some cans would have more solder on the inside than others. Further than this to solder quickly and with an economy of solder, with rosin as a flux, requires a skilful workman, whereas the beginner uses much solder, and at first, perhaps, hydrochloric acid instead of rosin as a flux. The acid, in contact with the solder, forms the very poisonous stannous chloride, which, in the hands of the beginner, is all the more likely to be used carelessly and get into the contents of the can. The manager of a canning factory makes such a distinction between a good and bad solderer that each man is often made to put his mark on each can made, so that it may afterward be identified.

As to the can itself, if pure tin alone were used, the formation of a poisonous stannous compound sufficient to produce marked symptoms, even if eaten for a long time, would not be possible, as has been absolutely demonstrated. Some innocuous stannous hydrate would always be present, however. On the other hand, if lead in any quantity is used as an alloy with the tin, then is lead poisoning likely to follow, provided enough is eaten, and over a considerable time. Especially is this likely to occur in goods kept for a long time, or when the contents are left in such a defective can exposed to the air, or when such cans and their old contents have been "reprocessed." These last can be detected, as there are then to be seen two soldered-up holes instead of one in the head of the can; the sound cans have but one soldered-up hole. The contents should never be allowed to stand long in the can after opening, especially in warm weather. The can should contain on the label the name of the manufacturer and place of putting up, and be labeled "Standard." If a can has rust about the cap, air has very likely got in and the contents decomposed and formed possible poisonous compounds with the wall of can or solder; hence, reject such cans.

These points, in connection with the symptoms in any suspected case of poisoning from canned foods, will enable the practitioner to make a diagnosis. From consideration of the above facts he will be able to give his patients a just estimate of the dangers of poisoning from canned food, showing that such danger is small if the above precautions are attended to. Considering the vicissitudes that canned foods must pass through under the hands of the can-makers, the solderers, and the tradesmen, with the chance of being "reprocessed," or kept for years before reaching the consumer, it is surprising that so few cases of poisoning therefrom have been reported.

Professor Hills stated that the reader had given an impartial *resume* of the literature of the subject, as it has appeared in the medical journals of the past few years. He criticised, however, the prevalent practice of attributing the symptoms which sometimes follow the ingestion of tinned foods to metallic compounds, without first ascertaining that the article ingested actually contains such compounds. It is not sufficient, moreover, to show that the food contains an unknown quantity of some metal. A quantity sufficient to account for the symptoms must be demonstrated before one is justified in attributing the symptoms to metallic poisoning. Symptoms resembling those of irritant poisoning not infrequently follow the ingestion of food which has not been preserved in tins, and in which chemical analysis has failed to disclose any irritant poisoning. Cases are also recorded in which tinned foods, free from metallic salts, have given rise to similar symptoms In these cases the symptoms could not have been caused by metallic irritants, and the speaker believed this to be true of a large majority of the reported cases of poisoning from tinned foods

Two facts are well established with reference to these foods First, they frequently contain traces of certain metals, they usually contain tin, not infrequently zinc or lead Second, symptoms resembling those of acute irritant poisoning, and even death have followed their ingestion It has not been proved in any authenticated case, so far as the speaker could remember, that the symptoms have been caused by the metallic impurity

It is important to bear in mind that the quantity of tin, lead, or zinc which a can of food contains is very small The quantity of tin, when present, usually ranges from a few one hundredths of a grain to one grain per pound, rarely approaching, however, the higher figure These amounts are not likely to give rise to symptoms of acute poisoning, though, it is true, but little is known regarding the poisonous action of tin compounds, if we except the chlorides and the oxide The speaker believed, however, that a quantity sufficient to produce harm is rarely present If present, he believed that it would be recognized by its taste, and the food thus contaminated be rejected as unpalatable Such cases, so far as there is any evidence, are rare Lead in tinned foods is derived either from the tinned plate or from the solder The quantity present in foods thus containing lead is too small to give rise to symptoms of acute poisoning Zinc is frequently detected in tinned foods Its presence is attributable to the use of the chloride of zinc solution as a soldering fluid The speaker could not recall any cases in which a determination of the amount present had been made He did not, however, deny the possibility of tinned foods at times, containing a sufficient amount of chloride of zinc to cause symptoms of acute poisoning, or the possibility of such symptoms having been caused by this substance He objected to attributing the symptoms in any case to chloride of zinc without a chemical analysis The probability of the occurrence of such cases must be slight, since the solution employed is dilute, and a small amount only is used on each can Through the carelessness of workmen, however, a quantity sufficient to produce symptoms might find its way into the food, but food thus contaminated would be rejected by reason of its disagreeable taste It has been suggested that the excess of hydrochloric acid in the soldering solution may act upon the tin, forming the poisonous chloride of tin If the soldering solution is properly prepared, and an excess is avoided in soldering the cans, it is not probable that a quantity sufficient to produce harm will be formed If present in injurious amount it would undoubtedly be recognized by its taste On the whole, these cases of acute poisoning as a result of metallic impurities in canned goods must be rare All the cases thus far reported are based on insufficient evidence

To what, then, are the symptoms to be attributed? Doubtless, in many cases, to idiosyncrasy on the part of the patient, in some cases perhaps to the decomposition of food It is possible that in certain cases poisonous ptomaines may have been developed in the food Finally, it must be borne in mind that cases of subacute poisoning may result from the use of copper utensils, or utensils containing lead, for the preparation of the food Cases of poisoning from these causes are no more liable to occur with tinned foods than with other foods if proper care is exercised The speaker thought that the principal danger to be apprehended from the use of canned foods was that of chronic lead-poisoning Such cases have been reported and are always to be feared when these foods are used continuously for a considerable time They are now used very largely in this way on ship board and in the army It is always a wise precaution to remove the food from the can as soon as the latter is opened, since the solution of the tin or lead may be favored by the presence of air Analyses suggest the probability that time may be a factor in the solution of tin and lead Foods which have been put up two or three years have been found to contain more of those metals than those put up more recently It is advisable therefore to avoid old cans

Dr Blodgett observed that several cases of supposed poisoning from canned foods had recently been reported in the English journals, and that several important hints had been given as to the character of the contents of the can The fact that the ends of the can are crowded outward or *bulged* is an indication that decomposition of the contained food may have occurred The presence of two punctures in the cover of the can, which would indicate that the food as originally put up was not properly prepared, but underwent a process of chemical decomposition accompanied by the formation of gases which caused the ends of the cans to be projected outward The top of the can is then perforated a second time and the gas allowed to escape, and a second drop of solder is then applied to the opening thus showing conclusively that the contents of the can were not perfectly preserved when first sealed In England it has been found that cans of improper food are often stripped of their paper wrapper and that the second puncture is then made upon the side of the can instead of at the end, and on replacing the wrapper upon the can, the second puncture cannot be detected

Professor Hills stated that the cases reported by Dr Johnson before the New York Medico legal Society were not proved, and should not be considered The statements of Dr Johnson rest upon pure assumption, and are not trustworthy The flux that is commonly used is a saturated solution of zinc in chlorhydric acid, and no free acid exists by which any deleterious effect could be produced It is desirable that, in cases of suspected poisoning from canned goods, a portion of the contents of the *identical can*, which is supposed to contain the poisonou substance, should at once be submitted for chemic analysis If, under these circumstances, poisonou ingredients or products are detected in appropriat amount, the claim against the foods might reasonably be entertained. Until this can be demonstrated, however, we must in most cases seek other causes for the unwholesome effects occasionally noticed after partaking of tinned or canned goods as articles of food.

Dr. White asked how long the family had subsisted on tomatoes before symptoms of poisoning were observed.

Dr. Doggett stated that tomatoes had been almost the sole and continuous article of food for two months previous to the occurence of sickness.

Dr. White said that it would be quite improbable that two families should take water from the same supply pipe and that lead-poisoning should occur in only one. The water must be excluded as the source of poisoning. We frequently notice that contaminated water will produce poisoning in some members of a family and not in others, but the freedom of one entire family from a disease which became general in another using the same water service would seem to indicate that the water supply was not the source of the poison.

Dr. Thomas Amory De Blois, then reported

TWO CASES OF RETRO-PHARYNGEAL ABSCESS.

Abscesses beneath the posterior wall of the pharynx should be interesting to every one, at least on account of the rarity of their occurrence, for whereas few have seen more than one or two cases, yet almost everybody has seen one. They should be quite as interesting to the general practioner as to the specialist, for they are more likely to occur in the practice of the former than the latter, on account of their usually being found in children, and of their being opened as soon as found. As to what constitutes a retro-pharyngeal abcess. We should carefully exclude the peritonsillar, or that which is found in the loose tissue around the tonsil, and in so doing might select the posterior pillar of the fauces as the anterior boundary; then any abcess posterior to these pillars, and situated beneath the pharyngeal wall, and from the vault of the pharynx above to the larynx below, should be included under this head.

It has been my good fortune to see five of these cases, two of which occured last month and within one week of each other, both being in very young subjects.

On the second of March, Dr. G. W. Galvin, being obliged to leave the city, requested me to see the child of Mrs. S., in South Street. I found the little boy, only three months old, lying on a lounge on his side. He was markedly anæmic, and breathed with great difficulty. The mother reported that the child had eaten nothing for twenty-four hours, and that during the preceding night they thought he would die in one of the paroxysms of dyspnœa, of which he had had several. What struck me particularly in the child was that the head was not thrown back, as I had expected to find it.

In the history of the case, as given by Dr. Galvin, he had found an enlargement which seemed to point internally; this disappeared, and two swellings were found on the same side of the neck externally. One of these he incised, but found little, if any pus; subsequently the tumor was found in the throat.

Placing the child in its grandmother's arms, with its back to the light, by the aid of the head mirror, and a very small teaspoon (for the arch of the jaw was to small to admit the smallest-sized tongue depressor) I gained an excellent view of a red swelling a little to the left of the middle of the pharynx, a large part being obscured by the tongue; there was also undoubtedly fluctuation on touch with the finger. Having with difficulty obtained permission to open the abscess, and after instructing the woman who held the child to reverse him, when told, as she would an hourglass, I got the point of a bistoury, well guarded with cotton, into it, and cut down till I reached my spoon. The child was inverted promptly, and the pus gushed out on the floor in large quantities, leaving no room for doubt that if the abscess had burst during sleep suffocation would have ensued. Having no syringe with me which would work, I had to wipe out the mouth repeatedly with a wet napkin.

The patient now seemed to be much weaker than before the evacuation of the pus; he was laid on the side with his head lower than his body, and occasionally a few drops of brandy and water were given, and finally the child took the breast. The following morning he was reported as being convalescent.

My second case, which I saw March 8th, was a patient of Dr. Disbrow, a female child of seven months, living in Columbia street, daughter of Mrs. H. The mother had been a patient of mine at the Dispensary about two years ago, and while pregnant had developed a peculiar and I suppose hysterical affection of the larynx, taking the form of aphonia, due to want of tension of both vocal cords; this persisted in spite of all remedies until after parturition, when it disappeared spontaneously.

Mrs. H.'s child was exceedingly pale and sick, but had been able to eat, and resisted with violent struggles all attempts to see the fluctuating swelling, which could be felt in the posterior wall of the pharynx, and which pushed forward the velum until the uvula stuck out almost erect. Only once before I cut was I able to sight the abscess, which, unlike the first one, was almost white, and stood in the median line; but this child's head was not thrown back any more than the other. I followed as far as possible my former procedures, except that in addition I had the father to hold the child's head. I think I must have been fifteen minutes trying to bring the abscess again into view, and when I did I cut exactly as I had before, except that the incision was not so long. The child was also turned head downward, and the mouth was syringed, the pus pouring through both nostrils, but there was no blood. On digital examination there appeared to be a second tumor below the first, which afterward seemed to drain off through the same opening, but it must have filled up again, for I heard of its opening spontaneously the next day. After the operation it appeared as if the child were about to go into collapse; the pulse could not be felt, the eyes closed, and she ceased to breathe; wine was given, also the breast after she had rallied a little, but she could not nurse. Yet I felt sure that none also recorded in which tinned foods, free from metallic salts, have given rise to similar symptoms In these cases the symptoms could not have been caused by metallic irritants, and the speaker believed this to be true of a large majority of the reported cases of poisoning from tinned foods

Two facts are well established with reference to these foods First, they frequently contain traces of certain metals, they usually contain tin, not infrequently zinc or lead Second, symptoms resembling those of acute irritant poisoning, and even death, have followed their ingestion It has not been proved in any authenticated case, so far as the speaker could remember, that the symptoms have been caused by the metallic impurity

The following morning he was reported as being convalescent.

My second case, which I saw March 8th, was a patient of Dr. Disbrow, a female child of seven months, living in Columbia street, daughter of Mrs. H. The mother had been a patient of mine at the Dispensary about two years ago, and while pregnant had developed a peculiar and I suppose hysterical affection of the larynx, taking the form of aphonia, due to want of tension of both vocal cords; this persisted in spite of all remedies until after parturition, when it disappeared spontaneously.

Mrs. H.'s child was exceedingly pale and sick, but had been able to eat, and resisted with violent struggles all attempts to see the fluctuating swelling, which could be felt in the posterior wall of the pharynx, and which pushed forward the velum until the uvula stuck out almost erect. Only once before I cut was I able to sight the abscess, which, unlike the first one, was almost white, and stood in the median line; but this child's head was not thrown back any more than the other. I followed as far as possible my former procedures, except that in addition I had the father to hold the child's head. I think I must have been fifteen minutes trying to bring the abscess again into view, and when I did I cut exactly as I had before, except that the incision was not so long. The child was also turned head downward, and the mouth was syringed, the pus pouring through both nostrils, but there was no blood. On digital examination there appeared to be a second tumor below the first, which afterward seemed to drain off through the same opening, but it must have filled up again, for I heard of its opening spontaneously the next day. After the operation it appeared as if the child were about to go into collapse; the pulse could not be felt, the eyes closed, and she ceased to breathe; wine was given, also the breast after she had rallied a little, but she could not nurse. Yet I felt sure that none of the discharge had entered the lungs, and on auscultation with the stethoscope they seemed to be quite clear of fluid. I tried all I could to rally the child, but when I left the house it seemed about an even chance whether she would live or die.

The next day, however, I received a letter from the father, stating that the baby was "playing on the floor as lively as a kitten."

Last year I mentioned a third case of pharyngeal abscess, which occurred at the Boston Dispensary, in a man, D. M., aged twenty-seven years, and whom I saw on the twenty second of November, 1880. He had what appeared to be an acute pharyngitis, but he returned on the 24th with his head a good deal bent backward, and a large swelling behind the pharyngeal wall, which fluctuated. I had never seen a pharyngeal abscess before, and when I passed a bistoury into it was very much surprised at the large amount of pus which flooded the patient's mouth and throat. I quickly seized him by the hair and forced his head down into a spittoon which was on the floor, and he was thus enabled to clear his throat and nasal cavities without any of it entering his larynx.

Soon after this I was allowed to see a case in the service of, I think, Dr. Haven at the Dispensary. A little child, perhaps two years old. The head was carried markedly back into the episthotonus position, and there was so much pain and so little fluctuation that I gave it as my opinion that it was a case of disease of the cerebral vertebræ, but it afterward went to the Children's Hospital, and was finally aspirated, I believe.

About a year ago I saw a fifth case in consultation with Dr. Galvin, the child was young, and the swelling was so near the posterior pillar of the fauces that I always felt some doubt as to its being a true pharyngeal abscess. Dr. Galvin cut into it while I was present, but got only blood, either that night or the next day he cut again and got pus.

According to McKenzie and the authorities he quotes, these affections are idiopathic. Bokai at least counts one hundred and twenty nine such out of one hundred and forty four cases, whereas Cohen, quoting from Gautier, states that "it appears to be idiopathic in some few instances only."

In the last volume of the Transactions of the American Laryngological Association, in the exhaustive article by Dr. J. O. Roe, of Rochester, on this subject, this gentleman quotes twelve different authorities who seem to hold twelve different opinions as to the causation of these affections. They range all the way from suppuration in the region of the perineum, by Nelaton, to chronic "snuffles," by Frankel.

In none of the five cases which I saw was there any assignable cause, there was no syphilis nor other constitutional affection that I could learn. None of the cases appear to have been well nourished, but no worse than is frequently found in that sphere of life. The hygienic surroundings were what appear to be inseparable from poverty in a large city.

In the first two cases which form the subject of this paper it will be observed the extreme prostration which followed the evacuation of the contents of the abscesses, in both cases the children luckily recovered, but would they have survived the operation had they been less strong?

Of course, incision is the procedure which most would follow in dealing with these cases, but may not death in some instances ensue from shock? Would aspiration be any safer than rapid evacuation? and if emptied by the aspirator, is not the probability of the abscess refilling much greater?

I should also like to draw attention to the fact that the heads in these two cases were not carried in what I always believed to be the "pathognomonic" position,—so that symptom was lacking.

One child was unable to swallow, while the other appeared to have no difficulty in doing so, although its abscess was larger and appeared to obstruct the pharynx more.

As to the incision, it has variously been advised to make it longitudinally, traversely from below, upward, etc., but it seems to me that the cut should be made from as near the soft palate as you can get, without injuring it down until you come to the depressor which will protect the tongue, and of course the more dependent portion of the abscess should be laid open, if possible.

The holding of a child with its feet in the air, or the forcing of an adult's head toward the floor are precautions worth observing, for even in the case of the one grown person mentioned, the liberation of the pus was so sudden and overwhelming that it was no easy matter to clear the throat quickly.

I have never seen a case of retro pharyngeal abscess due to disease of the spine, but it is this class that refill, recur, or do not get well. The idiopathic and the traumatic begin and end with the one attack.

Dr. F. H. Hooper stated that his experience in this rare disease comprised but few cases. Of these, one occurred in the Massachusetts General Hospital, and was brought to the notice of Dr. Hooper by Dr. Cabot. One case was seen in Vienna, and occurred in a male patient in the ward of Professor Schrotter. In this case there was great swelling situated low down in the pharynx, in which obscure fluctuation could be detected. Dr. Hooper operated by the aid of the mirror and the Schrotter bistoury, but did not succeed in evacuating pus. Professor Schrotter operated afterward, when it became apparent that the swelling was due to a hypertrophy of the thryoid gland, which extended completely around the pharnyx, so as to appear as a prominence behind, and had been incised. Fortunately the hæmorrhage was easily controlled. One other case was seen in Vienna.

Dr. Blodgett mentioned one case within his observation in which the nature of the disease was not fully recognized, and treatment was mainly expectant. After a period of four days the abscess suddenly opened spontaneously and a copious discharge of pus occurred, from which the patient was quickly suffocated and immediately died. Dr. Blodgett thought that too much stress could not be upon the necessity of quickly inverting the patient so as to allow the contents of the abscess to escape from the mouth, as the amount of pus was frequently much greater than could have been anticipated, and the danger of immediate death from suffocation is always present It would seem that in hardly another form of surgical disease was timely and judicious operative interference more urgently demanded than in cases of retro pharyngeal abscess

Dr Blodgett asked if necrosis of the vertebra or hypothic deformity were ever produced by a purulent process located in immediate contact with the vertebral column

Dr Du Bois replied that this has not been observed, owing doubtless to the acute character of the disease as well as to the fact that some form of acute meningeal inflammation would probably be induced by the invasion of the vertebral column in the rapid manner in which this would occur from a pharyngeal process, and that a fatal result would almost of necessity ensue before necrosis or exfoliation of the bony tissues could occur

ROCKY MOUNTAIN MEDICAL ASSOCATION

Fourteenth Annual Meeting

The fourteenth annual meeting of the Rocky Mountain Medical Association was held in the parlors of the St Charles Hotel, New Orleans, Wednesday, April 29th, 1885

The President, Dr George Sutton, of Aurora, Indiana, occupied the Chair, Dr John Morris, of Baltimore, Md , Secretary

The following members were in attendance Drs N S Davis, Parsons, Shively, Toner, Sutton, of Pittsburgh, Stormont, Harding, Hibberd, Helm, Pollock, Sutton, of Aurora, Ind , Bartlett, and Morris Honorary members present Mrs Hibberd, Mrs Helm, and Mrs Morris

The Secretary reported the deaths of three members during the year Dr A B Hovey, of Tiffin, Ohio, Dr George F Hilliard, of Evansville, Ia , and Dr J S Moore, of St Louis Mo

The President then read his address, which was a most interesting and scientific paper, embracing a geological and archæological study of the immense plateaus west of the Rocky Mountains At the conclusion of the address a resolution of thanks was passed, with a request that the address should be published in some scientific journal

The Association adjourned to meet in St Louis the first Wednesday in May, 1885

JOHN MORRIS, Secretary

LETTER FROM BERLIN

(FROM OUR OWN CORRESPONDENT)

Microscopical Notes—Imbedding

Imbedding in Paraffin The object may be hardened in any fluid medium, alcohol, Muller's fluid, osmic acid or corrosive sublimate Here it should remain for 24 to 48 hours Then remove to chloroform, oil of bergamot, oil of turpentine or oil of cloves Allow the object to remain here from one to 24 hours, until it is saturated Then remove to soft paraffin (a little turpentine or bergamot, or medium in which the object has been soaking, should be mixed with the paraffin, to make it softer and to keep it fluid at a low temperature) Place the vessel with the paraffine and object in an oven at as low temperature as it will remain fluid Allow the object to remain in the fluid paraffin from one to 24 hours Then place it in melted hard paraffin, let it cool after fixing the object in the position desired

To mount on glass slides—Objects colored in toto Pour a thin solution of shellac in alcohol over a clean glass slide, with a soft pencil moisten the surface on which you wish the section to rest with creosote, using the smallest possible amount Cut sections dry and place them in series on the surface moistened with creosote, with a fine brush or feather bring all parts of the section in contact with the creosote Dissolve the paraffin from the section by pouring benzine or xylol over it Cover specimens with Deck-glass and Canada balsam

Objects not colored in toto Cut the specimens and arrange in series on glass slides Add with fine pencil a drop of thin collodion to each section Let it dry Dissolve paraffin as before Place in absolute alcohol for 15 minutes Color sections on slide with any coloring solution Return slide and section to absolute alcohol, allow it to remain here ten minutes Mount in Canada balsam

Imbedding in Celloidin Buy the celloidin dry and dissolve it in equal parts of ether and absolute alcohol Let the specimens remain in absolute alcohol from one to three days, in order to dehydrate them Then put them into thin celloidin, alllowing them to remain there for 24 hours Pour off the thin celloidin and add thick celloidin In this the specimens should remain another 24 hours Remove the specimens to paper box or to cork Allow the celloidin to harden partially, add thick celloidin until the object is sufficiently colored Let it harden to the consistency of rubber Place in 70 per cent alcohol and allow to remain here until needed Cut your sections under alcohol and never allow them to get dry

How to bring out Endothelium Expose mesentery of frog and pour over it a 27 per cent solution of nitrate of silver while in the body Then wash in distilled water Dissect out mesentery and stretch it over a cork Pour over it a solution of coloring matter—hematoxylin — then remove it to alcohol Cut the sections under alcohol, and slip the section on to the cover glass, which is also under the alcohol Mount in balsam

Points to remember Sections that have been washed in distilled water must be mounted in gum glycerine, those soaked in alcohol can be mounted in balsam Acetic acid brings out nuclei, does not affect micro organisms Iodine colors nucleus Solution of silver nitrate, one-fifth per cent , stains the cement substance between the cells, also the nerve fibres and ganglion nerve cells A little salt solution will neutralize the silver solution Caustic soda swells up the elastic tissue fibres, but dissolves the non elastic fibres Liquor potassæ leaves micro organisms unaltered

Weigert's double stain. Mix together a saturated watery solution of aniline 100 cm. (aniline oil 1 part, dist. water, 3 parts) and saturated alcoholic solution of fuchsin, 11 cm. Stain well and wash in distilled water, then transfer to alcohol for ten seconds, and place in the following solution for two or three hours: Distilled water, 100 cm.; Saturated alcoholic solution of methyl blue, 20 cm.; formic acid, 10 minims. Then wash in alcohol, pass through clove oil and mount in balsam.

Koch's method of staining for tubercle bacilli. First stain in alkaline methyl-blue (mixed with a 10 per cent. sol. of caustic potash) for 24 hours, or for one half to one hour at a temperature of 40° C., then stain in a concentrated solution of vesuvin. Wash with water, then with alcohol, and mount in Canada balsam. Another method is: First filter and heat a watery solution of aniline oil. Add enough of a saturated solution of fuchsin to give a metallic lustre from the service. Let the cover glass remain here from two to five minutes. Then transfer to blue solution (saturated sol. of methylin blue in 20 parts nitric acid, 30 parts alcohol and 50 parts water) and let cover glass stay in about two minutes. Wash in distilled water, dry between two pieces of blotting paper. Mount in balsam.

Permanent specimens of micro organisms. Place the sections in a shallow dish with the coloring matter. Leave there until well colored. Take it out with a needle, wash it in distilled water, then in alcohol and leave it in the latter until the excess of coloring matter is removed. Spread it out on object glass and put a drop of oil of cloves on it. Drain off the excess of oil and add a drop of Canada balsam, in chloroform or benzine, and cover with cover glass. In leprosy, the specimen is stained with magenta, then washed in distilled water, then stained with methyl blue, washed and mounted. The micrococcus of gonorrhœa and of croupous pneumonia are best stained with methyl-blue and vesuvin. The anilin dyes in use are methyl blue, methyl-violet, vesuvin, Bismarck brown, magenta, fuchsin, rosanilin, gentian violet, Spille's purple, eosin, dahlia, purpurin, and iodine green. The washing is to be carried out in all cases, except with tubercle-bacilli and the bacilli of glanders, with distilled water, then with alcohol. Lustgarten's stain for syphilis is as follows: First harden in alcohol for twelve or twenty four hours, then place for two hours in a dye composed of eleven parts of a concentrated alcoholic solution of gentian violet and 100 parts of aniline water at a temperature of 104° F. Then wash with absolute alcohol, and place for ten seconds in a permanganate of potassium solution (1½ per cent.). Then transfer to pure sulphurous acid and allow them to remain until all excess of color is removed. Then wash in distilled water, and pass through the permanganate solution again. Then wash again in sulphurous acid, and so on until *all color* is removed. Mount in oil of cloves after extracting the water with alcohol.

In the course of a lecture not long ago, Dr. Grawitz said that the round or formative cells, in acute cases, came from the blood corpuscles, and in chronic cases from proliferation—a position which probably he would find some difficulty in proving. He was probably desirous of harmonizing the Cohnheim and Virchow schools, and did not wish to seem to be, even, lacking in respect for his great master. It certainly is possible that the formative cells may come from both the blood-corpuscles and the connective tissue. Time and time again I have seen the two kinds of cells, the one having all the appearance of leucocytes, while the second kind contain two or three nuclei. The epitheloid cells become stellate or spindle shaped. After a time these processes grow out and become converted into fine fibres, together with some of the substance of the cell itself, the rest of the protoplasm remains as the fixed connective tissue cell. Neighboring cells send out fibrillæ, which communicate and form fibrillated connective tissue.

H. R. P.

DOMESTIC CORRESPONDENCE

HYSTERO-CATALEPSY

Dear Sir:—Owing to the general infrequency of this disease, as well as the rarity of its coming under the observation of every practitioner, even in the most lengthened term of experience, I deem it incumbent upon me to report my case. Having had charge of one of our largest asylums for girls for the past seven years in which this young woman was raised from infancy to womanhood, now serving in the capacity of assistant, it was only within the past year that my attention was called directly to the unusual phenomena in her case.

She is about 30 years of age, of good general health, aids frequently in the washing and ironing of the clothes of the inmates, but not exposed, as there are permanent fixtures in the main building. She had been somewhat irregular as to her catamenia, often premised by and accompanied with pain, as in ordinary dysmenorrhœa. I had ascribed this condition somewhat to more or less dampness of the garments at her waist from splashing when washing clothes, and prescribed accordingly for the immediate relief of the trouble, and ordered suitable tonics during the inter-catamenial period. Yet her general health was always good, she always ate well, and complied promptly with the requirements made of her. I have never examined her *per vaginam*, since she is a virgin, I have never felt that I should destroy her virginity by the insertion of a speculum. The pathognomonic features being indubitable in such a case, even the least caution observed would detect them, and I imagine that the same could detect the artistic malingerer.

Since nothing is known of the pathology of this disease, it would be *apropos* to denominate it one of the neuroses. Manifesting itself as it does, coincidently with her catamenia, I consider the consociation of the two terms *hystero catalepsey*, suitable, both to define origin and nature of the disease. When I saw her in the midst of a cataleptic condition I found her to be a most perfect counterfeit of death, even the respiration was so slightly superficial that one would not detect it, and with a feebly soft compressible pulse To verify my diagnosis to the matron of the asylum, I lifted her arm in mid air, and releasing my hold, it remained until I forced it down by some little pressure, and likewise I elevated her right foot with the identical result The general rigiditas corporis was typical, just as instantaneous; she would utter a piercing shriek as if in pain, and toss about violently, and subside into a low moaning condition, ultimately in to a comatose state, when not violent in her seizures she would alternately laugh, cry, and talk at random Even the freely appearing menses would not cause an immediate arrest of the phenomena, yet to facilitate the flow, I would have stupes (*of turpentine and hot water*, ʒj Oj) applied to whole surface of abdomen, repeated conformably to her tolerance and restoration During the first attack, I gave her ½ gr morph sulph hypodermically, with controlling benefit, shortening the the attack The second attack was controlled by chloral and bromide of potash compounded in enema opii, repeated as indicated In each of her attacks or seizures, the duration was four or five days before perfect restitution was effected, and save an extreme prostration subsequently she suffers no inconvenience She is now at her post, and upon the next seizure, I will make more minute notes as to pulse, temperature, character of urine as also exact duration of attack from incipiency to termination I have placed her upon a strictly tonic treatment

THE INTERNATIONAL CONGRESS COMMITTEE

EDITOR JOURNAL AMERICAN MEDICAL ASSOCIATION

Dear Sir —I notice in the report, as published in the JOURNAL, of the proceedings of the meeting of the Committee of the American Medical Association on the International Medical Congress, that my name appears among those present at the meeting I was not present, and I do not approve of what was done at the meeting Yours truly,

WM PIERSON

Orange, N J, July 8, 1885

HYDATID TUMORS OF THE BRAIN

Sir —Allow me to call attention to two points in the paper by Dr R Harvey Reed, on "Hydatid Tumor of the Brain," published in the JOURNAL of July 4th (1) The term hydatid tumor should be, and usually is, limited to the echinococcus cyst, the larvæ of the Tænia echinococcus or Hydatid tape worm The terms "cysticercus" or "measle" should be used in describing the larva of the Tænia solium (2) The cases reported by Dr Reed cannot as they stand be accepted as instances of hydatids or of cysticerci The description of the cysts is too meagre, and a microscopical examination does not appear to have been made, without which it is in many cases impossible to determine the parasitic nature From the position of the cysts in the lateral ventricles in each case, it seems probable that Dr Reed has been dealing with the not uncommon hydatidiform cysts of the choroid plexuses, structures which have on several occasions been sent to me as possibly parasitic

Interest in the subject of echinococcus disease in this country must be my excuse for thus encroaching on your space I am, yours etc,

NECROLOGY

WILLIAM T WRAGG, M D

The custom of commemorating, in some form the death of one who has impressed his fellows by his virtues or his actions is of very ancient date, and its continuance at present is not only evidence of its propriety, but of its filling a want that the mind of every person admits to exist In reviewing the life of him who so lately has been taken from amongst us, one cannot fail to be reminded that death has removed from our ranks a faithful, efficient and esteemed brother, one who loved the profession, sought its advancement and respected all its usages

On the 30th of May, 1885, Dr William T Wragg, one of the oldest and most esteemed physicians of the State of South Carolina, died at his residence in the City of Charleston, S C He was born near Georgetown, S C, removed with his parents, Major and Mrs Samuel Wragg, to Charleston in 1819 He entered the South Carolina College, where he graduated in 1827 He chose the medical profession as his pursuit through life, entered the office of Dr J M Campbell as a student, and attended the "Medical College of the State of South Carolina" for three years, graduating at that institution in March, 1830 In the following May he went to Paris with Dr J E Holbrook, professor of anatomy in this college, where he pursued his medical and surgical studies, and after visiting all the hospitals, made the wards of Hôtel Dieu his constant care, every day found him in attendance at the visits and clinique of the greatest surgeon and diagnostician of his age, Dupuytren Here also lectured at that time the great physiologist and vivisector, Magendie A few weeks after his arrival the famous revolution of July, 1830, broke out, and hundreds of men, women and children filled the wards of Hôtel Dieu, with every kind of wound, gunshot, sabre, bayonet, cannon ball, and wounds from stones and other missiles Here Dr Wragg learned those lessons which gave him success in his practice in after years

Soon after his return home, Dr Wragg entered upon the practice of his profession, and continued it successfully to the time of his death In 1847, Dr Wragg was made treasurer of the "Roper Hospital Fund," a fund bequeathed to the Medical Society of South Carolina by Mr Thomas Roper with which to build a hospital His administration of this office shows how careful he was of trust reposed in him, and how his judicious management has enabled the trustees to execute the testator's benevolent intentions The fund was under Dr Wragg's management from 1847 to the day of his death—37 years—

and notwithstanding unavoidable losses during the late war, is at the present time nearly double the amount of the original sum

He was an able and constant contributor to the *Charleston Medical Journal* He was conspicuous for his erudition and professional acquirements, while his purity and devotion of character, his urbanity and professional courtesy were known and appreciated by all Dr Wragg was held in high esteem by the medical profession, and at a meeting of the physicians of the City of Charleston, on account of his death, after eloquent remarks by some of his most intimate friends, the following resolutions were unanimously adopted

Resolved, That in the death of our brother and ex-President, Dr Wm T Wragg, this Society has sustained the loss of an eminent and esteemed member

Resolved, That our sympathies are extended to his family in their great bereavement

Resolved, That in consideration of his faithful services as custodian of the "Roper Fund" for thirty-seven years the Society erect a tablet in this Hospital to his memory

Resolved, That a copy of these proceedings be transmitted to the family of the deceased, and to the daily newspapers of the city

MISCELLANEOUS

College Changes —Recently Dr N Senn, of Milwaukee, Wis , has accepted the Chair of Principles and Practice of Surgery, previously occupied by Dr R L Rea, in the College of Physicians and Surgeons, of Chicago, and Dr Christian Fenger the Chair of Clinical Surgery in the same College

In the Chicago Medical College, Medical Department of the Northwestern University, Professor E O F Roler has been transferred to the position of Emeritus Professor on account of continued ill health, and Dr W W Jaggard has been appointed Professor of Obstetrics, the duties of which position he had discharged for the last two years with the highest degree of satisfaction on the part of both Faculty and students

Dr N S Davis, Jr , Lecturer on Pathology and Pathological Anatomy, will fill the place vacated by the resignation of Prof Fenger He has just returned from a few months stay in Vienna and Heidelberg, where he devoted his time almost exclusively to a study of morbid anatomy and pathological histology

International Notification of Infectious Diseases —At the recent International Sanitary Conference held in Rome, two propositions relating to international notification of cases of infectious diseases were passed at the last session of the Technical Subcommission These propositions are as follows

1 The Technical Committee expresses the wish that the International Conference affirm the necessity of publishing a bulletin of international statistics for each important city, a bulletin on a uniform plan, and publishing each week the total deaths and the number of deaths caused by each infectious disease, and particularly by cholera and by yellow fever

2 As concerns cholera and yellow fever, notification of the first cases which appear in different localities, and particularly in maritime ports, should be immediately sent by telegraph to the various governments

The application to yellow fever was introduced by the delegate from the United States as an amendment, the proposition as first reported having taken no account of this pest of the West Indies, which from an American point of view is quite as worthy of consideration as is the Asiatic pestilence which has almost exclusively occupied the attention of the International Sanitary Conference of Rome —*Medical News*, June 27, 1885

Prizes of the University of Amsterdam —The Faculty of Medicine of the University of Amsterdam has given the subject of the prize dissertation for 1886 as "The Therapeutics of Iron and the Absorption of Iron Sutures" The essays must be delivered to the Secretary of the Senate by May 1886, and the result will be announced, and the gold medal awarded to the author of the best essay in September, 1886

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM JULY 4 1885 TO JULY 10 1885

Captain Valery Havard, Assistant Surgeon, assigned to duty at Ft Wadsworth, New York Harbor

First Lieutenant M C Wyeth, Assistant Surgeon, assigned to duty at Ft Wayne, Mich (S O 140, Dept East, July 2, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING JULY 11 1885

Byrnes, J C , Passed Assistant Surgeon, detached from the "Powhatan" for duty at Navy Yard, Norfolk, Va

Cordeiro, F J B , Assistant Surgeon, to the "Powhatan" as relief of P A Surgeon Byrnes

Curtis L W , Assistant Surgeon, to Philadelphia for examination preliminary to promotion

Drennan, M C , Surgeon, placed on waiting orders

Fitzsimmons, P , Surgeon duty on Receiving Ship "Franklin," Norfolk Navy Yard continued until July 1, 1886

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED JULY 11 1885

Fessenden, C S D , Surgeon leave of absence extended sixteen days, on account of sickness, July 1 and 9, 1885

Bennett, P H , Assistant Surgeon, granted leave of absence for twenty two days, July 9, 1885

CORRIGENDUM

Sir —In writing to the *Lancet* on the diagnosis of submersion during life or after death I made a mistake in translating the French word mousse ' to moss which is evidently incorrect It should be *froth* In fact the correction was made in the *Lancet* of the 21st March p 547, which I must ask you to be good enough to correct also as I find the article referred to has been reproduced in the Journal of May 23

I am Sir
Yours obediently,
Paris Correspondent of the Lancet

EMMET'S OPERATION WHEN SHALL IT, AND WHEN SHALL IT NOT BE PERFORMED?[1]

BY GUSTAV ZINKE, M D ,
OF CINCINNATI OHIO

MR PRESIDENT —Trachelorrhaphy, or Emmet's operation for the cure of laceration of the cervix uteri, and its consequences, is recognized by many, in this country at least, as a measure productive of much good, and a great advancement in gynecology Though the English and the Germans are slow in accepting it, and although in France we find as yet not one who will openly endorse it, the operation seems to be, nevertheless, a legitimate and permanently fixed resource for the relief of some lacerations of the cervix and their results And how could it be otherwise? The injury is readily diagnosticated, and its mischievous influences easily appreciated and recognized as such by skilful men What treatment could be more simple, more rational, and more effective? There should not be any doubt upon this question Still there are some, even in this country, who are disposed to look with disfavor upon the operation So much has been said and written on this point by the ablest gynecologists of this country, that no argument of mine is needed here Experience and time will accomplish what argument has so far failed to do With the knowledge I have upon this subject, in my judgment there is but one point left to be discussed, and that is *When shall we, and when shall we not perform this operation?* Upon this there is great diversity of opinion To aid in the removal of this dissension and establish greater harmony, is the object of this paper For this purpose I have addressed to a large number of our most prominent gynecologists and surgeons of this country and abroad, a letter containing a number of questions, calculated to elicit their latest opinion regarding this subject I sent it in printed form, with sufficient space after each question to allow a concise answer I adopted this course to obtain an answer from all as nearly alike as possible, and to the point I also took pains to send these questions to those known to be more or less opposed to the operation, or, if you please, "not much impressed with the importance of trachelorrhaphy"

The following is the letter which accompanied the questions as seen in the record

CINCINNATI, O , February, 1885

Dear Doctor

Owing to the great diversity of opinion respecting the beneficial effects and proper sphere of usefulness of EMMET'S OPERATION, I have concluded to write an essay upon this subject, which is to be read before the American Medical Association, convening at New Orleans, La , the latter part of April next In order to make the paper complete and valuable, I have deemed it wise to obtain the latest opinion of those men in the profession, in this country and abroad, who, by reason of their position and professional attainments, are best qualified to judge I am well aware that this subject has been discussed and written upon from every aspect by many , but it must also be admitted that it has never been fairly decided, indeed, that to day it is shrouded in greater uncertainty than ever It is my desire to put on record the statements of all who will be kind enough to answer and present the same in concentrated form, from which those interested in the matter now, and hereafter, may draw their own conclusions, which, I hope, will harmonize more than at present Hoping that you will consider the importance of the subject, and favor me with an early reply, by answering briefly the questions in the accompanying blank, I remain,

Yours fraternally,
GUSTAV ZINKE, M D ,
413 Elm St , Cincinnati, O

The letter, as well as the questions, will need explanation in so far as they refer to the beneficial effects and proper sphere of usefulness of Emmet's operation, and not directly to what the caption indicates Anyone looking over the questions and answers, however, as given in the tabulated record, will be convinced that I could not have adopted any other way to arrive at conclusions at once unbiased and free from the suspicion of being one-sided I could not have asked simply and solely When do you and when do you not operate? The answers to the questions as propounded, put each one on record fully, by giving his reasons why he would in one case, and not in another, or, perhaps, never perform the operation

Let us now consider these replies and see if from them we may gather sufficient evidence to decide when we should and when we should not operate

DR GUSTAV ZINKE —I have the highest regard for Emmet, and have learned much from his works But "Emmet's operation" I look upon as entirely unnecessary I perform the same only when, by retroflexions, the laceration of the cervix interferes with orthopædic treatment I can furnish many cases in which women, in spite of extensive tears, were and remained perfectly well, that pregnancy was not interfered with, and that the rents caused absolutely no complaint For this reason I do not perform this operation, and I am firmly convinced that in a few decades it will be forgotten

With many respects, FRITSCH
Breslau, March 27, 1885

---

[1] Read in the Section on Obstetrics and Gynecology at the Thirty sixth Annual Meeting of the American Medical Association

DR GUSTAV ZINKE, Cincinnati, O —*Dear Doctor* —I have so recently gone over the whole subject of laceration of the cervix in the third edition of my book, just published, that I have nothing more to add I have there answered all the objections that have been brought against the operation Little more is to be said on the subject until the profession has carefully carried out my directions as based upon over twenty years of experience and close study Where there has been failure to gain the results I have claimed, the burden must rest on the operator to show the cause

The operation has long since passed out of my hands, and so fully endorsed that I have no fear for its future The great point is to check the abuse, which is fearful Everyone feels competent to perform it, it is done without the proper preparatory treatment, and with no special purpose I believe in nine cases out of ten, where it is done, or attempted, the execution of the operation is defective and without any benefit to the patient You have here a most fruitful field for your paper, but to discuss the merits of the operation within its proper range, is futile Yours truly, T A EMMET

89 Madison Ave , N Y , March 5, 1885

DR GUSTAV ZINKE, Cincinnati, O —*Dear Doctor* —I have not as yet been impressed with the great importance of lacerations of the cervix—excepting where they are extensive My operations have been confined to the latter class, and the results have been satisfactory Respectfully,

Rome, Ga , March 2, 1885 ROBERT BATTEY

DR GUSTAV ZINKE, Cincinnati, O —*Dear Sir* —As I have had no occasion myself yet to perform Emmet's operation, I feel scarcely justified in giving an opinion, and am not in a position to answer the queries in the form which accompanies your letter My experience is drawn only from a few cases in which I have seen Prof Simpson operate, and would watch the progress of the cases

There is no evidence that a lacerated cervix is in itself a condition of much importance in its relation to cervical catarrh and cellulitis it is of importance I fancy that the cellulitis we often see, especially in the left broad ligament, is due to slow septic absorption from the laceration , so also the ectropion will keep up, if not cause cervical catarrh On the other hand, lacerations are so frequent that we must look on them almost as a physiological occurrence, just as we do a *slight* perineal laceration Yours faithfully,

A H FREELAND BARBOUR

Edinburgh, March 17, 1885

DR ZINKE —*Dear Sir* — I regret that I have no statistics to aid you in your very valuable inquiry as to the merits of Emmet's "op " I have operated very little My patients do not come to me from abroad, and consequently will not submit to ulterior measures, as those will who go to men of more reputation I have seen some cases in which I thought it desirable — many where it would have been done by others, I think I have too few data to feel satisfied in my own mind, but my impression is that there are cases of unhealed laceration (ectropion) *demanding* the operation, and for those cases it is a great improvement

As to the *cicatricial tissue* doctrine, I feel very doubtful, and so expressed myself in review of 1st edition of Emmet's work (*Am Jour Med Soc*) Yet in last edition he brings many *facts* in support I operated in a case week before last—repaired cervix and peritoneum at same time I had exhausted local and general treatment in the case, and nearly two years ago advised the operation, which she then refused Three days after operation, she was free of back ache for the first time in months Of course I am waiting with great interest the ultimate result, for the ache had returned somewhat when I last saw her

There has been a wonderful change of doctrine by Emmet as to the operation, to which I call attention in review of 3d edition, to appear in April No *American Journal*

If you use this, please use no name

I am very truly yours, ———

March 1, 1885

Question 1 Do you believe lacerations of the cervix uteri to be an important factor in uterine and pelvic disease?

Wm Goodell, Ellwood Wilson and Charles Meigs Wilson, of Philadelphia, J Taber Johnson, of Washington, David Prince, of Jacksonville, Ill , Willis P King, of Sedalia, Mo , Wm H Taylor, of Cincinnati, W H Baker, of Boston, E W Jenks, of Detroit, T B Harvey, of Indianapolis, J Byrne, of Brooklyn, Chrobak, of Vienna, and W T Howard, of Baltimore, answer "Yes, ' or "I do "

T Gaillard Thomas says Yes, decidedly so

Geo T Engelmann It is one of the conditions which facilitates and assists the development of certain diseases directly leading to other

A Reeves Jackson When sufficiently extensive, yes

W H Byford I do when attended by chronic subinvolution or chronic congestion, not otherwise

Herbert M Nash, of Norfolk, Va My observations in the past twenty years force me to the confirmed opinion that laceration of the cervix uteri is frequently a most important factor in both

G H Lyman, of Boston I do most emphatically, especially if there be eversion

R S Sutton, of Pittsburg It is very frequently so It is often the prime factor

Paul F Mundé, of New York Most decidedly None more so in certain selected cases

Ely Van de Warker, of Syracuse Only when of such extent as to become a persistent focus of irritation

James B Hunter, of New York I do—one of the most important

Chaucy D Palmer, of Cincinnati I most certainly do

M D Mann, of Buffalo Very important and common

J Mathews Duncan, London, Eng "No "

Thad Reamy, of Cincinnati Yes, without doubt

P J Murphy, of Washington The deeper lacerations owing to impeded circulation may be the cause of pelvic disease

Wm T Lusk, of New York In certain cases, Yes

W Gill Wylie, of New York Yes, when the cervix torn is diseased—say cystic degeneration, etc , and it may become diseased after being torn, say in puerperal septicæmia, etc

I E Taylor, of New York Not necessarily By removing the pathological condition of the cervix uteri, whatever that may be, by the treatment your own judgment and experience may dictate, the laceration will be either perfectly overcome, or so much so that the laceration will not sustain the pathological state previously existing, and the laceration, whether it is a deep unilateral one or not, will be restored, and the length of the os tincæ will be diminished so much as to present almost a natural appearance

Q 2 Do you believe fissures of the cervix uteri a cause of uterine and pelvic disease?

A Reeves Jackson, Charles Meigs Wilson, David

Prince, C D Palmer, and E W Jenks, answer "Yes "

Engelmann answers Rarely

Gaillard Thomas Yes, but to a less extent

Ellwood Wilson says "Sometimes "

Nash May be a cause

Lyman I do, but to a less degree than the former

Sutton answers If deep

Mundé The smaller the rent or fissure the less, as a rule, its pathological significance

Van de Warker I have rarely seen mere fissures cause pelvic symptoms

Johnson I think the pathological and reflex disturbances are large in proportion to the extent of laceration, but not always

Hunter Not necessarily unless there is cicatricial tissue

W P King Not necessarily, but in some cases I have known a small fissure with granular erosion to cause severe reflex pains

Goodell Fissures, if skinned over, do but little harm, and I rarely touch them

Mann If by fissures you mean slight lacerations, I do not May be only slight laceration, showing but much deep scar tissue which will do great harm

Duncan, Lusk and Murphy say "No "

Wm H Taylor By "fissure" I understand less than "laceration," therefore less important

Baker If sufficiently extensive I do

Reamy Yes, to some extent

Harvey I do so far as pain and nervous disturbauce are concerned, but not attended with so much displacement

Byrne Not invariably, but frequently

Chrobak Yes, but in a different way

Howard As distinct from lacerations, only exceptionally

Wylie May not degeneration of the mucous membrane resulting in atrophy, contraction, and hyperæsthesia, as in imperfect development may?

I E Taylor "The same as above "

Question 3 State your theory in what manner a lacerated cervix will or may cause disease of the uterus, its surrounding tissues, and in parts remote

Thomas By creating local hypertrophy and glandular disease and by reflex influence

Engelmann Destruction of sphincter muscle leads to subinvolution—the open surface—exquisitely sensitive and irritable—leads to reflex symptoms by reason of friction—and inflammation by absorption

Jackson The exposure of the intra cervical structures to the vaginal secretion excites inflammation, first of the endometrium, secondly of the parenchyma

Byford I believe it perpetuates subinvolution and its consequences

E Wilson By allowing the uterus to sag downward in the pelvis and by the ectropion of the cervical mucous membrane it acts as a constant source of irritation, preventing involution The general reflex symptoms are more marked than the local ones

C M Wilson By preventing involution, acting as a constant source of irritation, and causing disturbances of general health, as manifested by the gravity of reflex symptoms

Nash In the majority of cases it seems to be the cause of irritation followed by both cervical and corporeal endometritis, erosions, profuse leucorrhœal discharge, and in my opinion these conditions forerun or may distinctly cause cellulitis and even pelvic peritonitis Displacements are common, and they are sometimes attended by numerous and annoying reflex symptoms

Lyman Local congestion of the body and mucous lining of the uterus, with neuralgic pains, hystero neurosis, by reflex action on distant parts, etc I believe all such should be repaired, if only as a safeguard against epithelioma

Sutton It arrests involution, causes catarrh of the canal, prolapse of the lining of the canal of the cervix, congestion of the entire cervix, prolapse of the uterus, retroversion, drag upon the round ligaments, congestion of the cellular pelvic tissue, constipation, nervous phenomena, vesical irritation, indigestion, backache, pains in the groins, etc

Mundé First, subinvolution of the uterus, then hyperæmia, then menorrhagia, or, first, subinvolution, then hyperplasia, or, attendant on subinvolution and hyperplasia, chronic eversion, hyperæmia and hyperplasia, or, immediate or remote pelvic cellulitis, peritonitis or lymphangitis Finally, epithelioma of eroded lips

Van de Warker By acting as a persistent focus of local irritation, thus inducing a morbid degree of uterine and pelvic hyperæmia

Johnson It causes endometritis, chronic cellulitis, favors subinvolution and all its evil effects Displacements on account of increased weight and size, and relaxed supports Leucorrhœa, cervical and uterine catarrh Increases quantity and frequency of menses By irritation and congestion favors abortion, predisposes to epithelioma, and causes many reflex nervous disturbances

Hunter By impairing the circulation By keeping up engorgement of uterus, and thus causing displacements, etc

Prince By constant irritation inducing local chronic inflammation, and by reflex action, hyperæmia and hyperæsthesia of near and sometimes distant parts through reflex action

King 1st By causing septic poisoning when recent 2d By acting as a point of irritation, causing pelvic congestion 3d Granular erosions, by failure to heal 4th Laying the foundation for epithelioma by degeneration of granular tissue

Palmer By delaying and preventing complete involution, creating erosions, granular degeneration of the cervix, and eversion of the cervical lips, and finally, hyperplasia, cystic degeneration, uterine displacement, and it may be epithelioma

Goodell By its keeping up an irritation of the uterine organs, and by an afflux of blood to them, causing growth, hypertrophy, etc

Mann In several ways, by causing cellulitis, subinvolution, endometritis, hypertrophy of neck, reflex action on distant organs, displacement, etc Believe it to be a common cause of cancer of cervix

Duncan It may be the seat of local irritation—so called ulceration

Taylor (Cincinnati) Keeping up engorgement, irritation, or pressure upon nerves, exhausting discharges

Baker By occasioning pelvic cellulitis, subinvolution of the uterus, hyperplasia of cervix, and increasing the tendency to the development of cancer of the cervix uteri

Jenks Ectropion and attrition of the everted lips furnish a constant source of irritation, causing congestion, connective tissue growth, and retarding involution and reflex symptoms, immediate and remote A laceration which has healed wholly or in part, may cause symptoms like the above on account of cicatricial tissue in which nerves are involved

Reamy Arrests involution by two or more processes, viz Disturbs normal nervous function 2d, the processes of repair of the injury which nature has to set up demand so much blood in the tissues as to prevent the fatty degeneration essential to involution

Harvey Fissures and slight lacerations cause inflammation, with exacerbations at the menstrual epoch More extensive lacerations cause cystic degeneration, hypertrophy, induration, displacements, and all kinds cause cellulitis, reflex irritation in remote parts, and predispose to epithelioma

Murphy A deep laceration of the cervix uteri interferes with the circulation of that organ, gives rise to hyperplasia, prevents involution, and by these means will induce hypertrophy, and may give rise to any one of the displacements frequently accompanying a lacerated cervix

Byrne Directly by its retarding involution, and more remotely as a cause (frequent) of abortion

Lusk By leading to disease of cervical and often corporeal mucous membrane Hence catarrhs, hæmorrhages, uterine enlargement, etc Many patients suffer from forms of remote reflex neuralgias, but these are not constant

Chrobak The effect of extensive laceration consists in the irritation as well as inflam of the param, perhaps, too, in the changes of the cervical mucous membranes resulting from the injured cervix and its exposure to the vaginal secretion

Howard When a laceration is accompanied by catarrhal ectropion of the cervical mucosa, this is increased by the attrition of the inflamed surfaces during respiration and locomotion, and this constant source of irritation creates reflex disturbance

Wylie If diseased when torn it will not heal, but evert swell, and prevent involution, etc Or if torn and infected by sepsis it may cause septicæmia, either local or general

I E Taylor Laceration of the cervix uteri, when treated by closure before attending to the treatment of the pathological condition, unless it is directly after the laceration, an acute laceration will not succeed, and even then I have my doubts whether it will not produce more trouble than when the operation is deferred till after convalescence If the laceration is so severe as to produce a secondary hæmorrhage—which I should consider as exceptionally rare, then a closure may be attempted If not, then the operation should not be performed, for in very many cases, if there has been a slight laceration, the patients have perfectly recovered, especially if proper treatment is adopted

The substance of these answers is about as follows

1 Septic poisoning at the time of its occurrence
2 It causes pelvic cellulitis
3 “ “ “ peritonitis
4 “ prevents involution
5 “ acts as a point of irritation
6 “ causes pelvic congestion
7 “ “ cervical and corporeal endometritis
8 “ “ profuse leucorrhœal discharge
9 “ “ displacements of the uterus
10 “ “ erosions and eversion
11 “ ‘ hyperæmia }
12 “ “ hyperplasia } of cervix as well as body
13 “ “ cystic degeneration
14 “ “ numerous reflex symptoms, especially from irritating cicatricial contraction
15 “ “ menorrhagia
16 “ “ sterility, by preventing conception, and by causing abortion
17 “ “ lays the foundation of epithelioma

No one present, familiar with this subject, will expect me to discuss the manner or the order in which one or all of these consequences may arise, every one of them seems to be conceded as being a natural result of laceration of the cervix uteri, and have been discussed at length in the latest text books (especially by Emmet and Thomas), in the *American Journal of Obstetrics*, and in the reports of the American Gynecological Society, also numerous original articles (read before the various societies all over the country) can be found, together with the discussion that followed their reading So profuse is the literature regarding the results of this accident, that it would be imposing upon good nature to cite the names of all the authors, and therefore I chose simply to refer to the books and journals in which most of the writings on this matter can be found

4 Q Do you believe laceration of cervix a cause of sterility?

Jackson, C M Wilson, Sutton, Van de Warker, King, Palmer, Goodell, Baker, Jenks, and Byrne, answer simply in the affirmative Thomas says, “sometimes, unquestionably”, Engelmann, “frequently”, Byford, “only when attended with the morbid conditions mentioned before”, E Wilson, “yes, if extensive”

Nash answers I do, in some cases I have known abortions to occur from this cause Lyman says Not necessarily, but often so Mundé Yes, if there is cervical catarrh (as usual) or cicatricial contraction of cervical canal Johnson In many cases by producing conditions named in answer to 3d question In some cases no effect seems to follow Hunter thinks that it is “often a cause of miscarriage”

Prince answers, “sometimes”, Mann, “most certainly”, Duncan and Murphy answer, “no” Taylor says, “only if extensive” Reamy, “in many cases” Harvey, “I do, although many conceive” Lusk, Not as a rule May lead to abortions Chrobak Yes, but mainly in consequence of complications Howard In some cases, certainly, but not in all" Wylie If diseased sufficiently to *at all times* cause acid or abnormal secretions

I E Taylor By no means I have several cases at present in my private practice whom I have attended in several confinements, and who had partial laceration, and a few up to the vaginal junction have had children, and one of them every fifteen months They were safely delivered, and no further laceration occurred In some of the patients who became widows, and others not having any more children, the laceration has healed and the cervix presented a more natural appearance In a few the cervix has become in form and appearance natural This morning two cases were seen, and it would be a question with some whether the women had a child from the appearance of the cervix The os tincæ has either assumed the round, small opening, or a small transverse slit

Seventeen answer with "yes," and three with "no" simply, while the others qualify an affirmative reply by adding "if extensive," "sometimes," "if there is profuse catarrh or cicatricial contraction of the canal," etc Sterility as an effect of laceration, has been violently assailed and ridiculed by some, but V A Hardon, *American Journal of Obstetrics*, 1881, in an excellent paper, describes in a striking manner how a lacerated cervix may be the cause of disease and sterility, and require sewing up for a cure, and how a cervix slit open by the knife to cure sterility, remains inert as a factor in disease and accomplishes the end desired There is no doubt that we see instances, occasionally, of even extensive lacerations of the cervix in which pregnancy occurs and is continued to the end of gestation, but these are, seemingly, exceptional cases I have seen such cases, they all had aborted before, however, and did abort again, though they used great care, during gestation

5 Q Do you believe that Emmet's operation, if performed early and properly, will, to some extent or entirely, prevent uterine and pelvic disease?

Jackson, C M Wilson, Prince, Baker, Jenks, and Byrne answer, "Yes" Duncan answers, "No" Thomas says In most cases Engelmann It will certainly prevent such diseases as are dependent on laceration Byford Yes After its complications have to a great extent been cured by preparatory treatment E Wilson Yes, usually Nash I do, hence advocate an early operation, though my cases have all been operated on for the relief of distressing results Lyman says I know it will prevent such diseases as would supervene if left untouched, and in consequence of the laceration itself See answer 1 Sutton says It may do immense good Mundé answers, Without doubt, in well chosen and proper cases Van de Warker Where the operation is indicated, I believe it to be curable

Jos Taber Johnson says I believe it will to some extent, or entirely prevent such uterine or pelvic diseases as are often sure to follow its occurrence We see, however, all the above named and other uterine and pelvic diseases where no laceration exists King Yes, excepting when disease of the pelvic organs immediately follows the laceration Palmer Yes, in properly selected cases Goodell I think it will, to a great extent, do so Mann Yes, unless cellulitis has occurred in childbed Taylor To some extent

Reamy In many cases prevent, in some cases cure Will always do good in properly selected cases, properly done But the most experienced gynecologist may now and then be deceived as to which are proper cases Harvey I do, where no other causes supervene, and I believe that slight laceration in time produce the so called "Cervical Metritis" ulceration and subinvolution and that the earlier the operation, the greater the success

Murphy I believe that uterine and pelvic disease always accompany a lacerated cervix, and ought to be relieved before the operation is performed Lusk answers Don't know Many patients with lacerations have no disturbances resulting I have only operated when symptoms made it necessary

Chrobak I regard Emmet's operation as one of the best and most certain for preventing disease of the uterus

Howard I do But if done too early it is apt to fail, and may even increase the mischief, while if badly done, it had better not be done at all No operation is more abused, or oftener badly done

Wylie In some cases, but preparatory treatment is nearly always needed, and it is by removal of diseased tissue rather than restoring continuity that a cure is effected

I E Taylor, of New York If it is in a recent case, I do not If the laceration is *bilateral* or *tripod*, without overcoming the diseased condition of the cervix, to some extent, or completely, then the operation for closure I do not believe will prove as successful and as beneficial till the pathological condition is treated and restored When this is accomplished, the laceration will be reduced in size, if it had been deep long, a more just estimate could be formed whether the bilateral should be treated by closure or not, and the tripod in the same manner If the lacerations, bilateral or tripod, should have reached the vaginal junction, which is very rare, I believe and the diseased condition of the mucous membrane not heal perfectly, and there is an eversion of the labia of the cervix, which is most generally the case, although eversion may occur from a positive or relaxed condition of the cervix, without laceration In that class of cases I have preferred amputating the anterior and posterior labia, or the three points of the cervix (the tripod) Believing that this surgical method is far better, and more simple than the attempt at closure for the bilateral or tripod lacerations After the removal of the parts the cervix heals up, and leaves a perfectly natural appearance of the cervix, cleanliness being only resorted to, and not covering the amputated stump as Syme has done I will not enlarge on this point, but refer you to my monograph in Bellevue and Charity Hospital Reports for 1876, on "amputations of the cervix uteri in procidentia uteri, and complete eversion of the cervix uteri," also, Vol 1, Transactions of the American Gynecological Society, for remarks "on

Emmet's Paper on Flexions " Emmet himself was much opposed to amputation of the cervix, except in special pathological conditions, and adopted Syme's method of covering the stump by the mucous membrane In a clinical lecture reported by Coe in the *American Journal of Obstetrics*, February number, 1885, page 174, he says, in reference to the treatment of lacerated cervix "I desire to say here that I have been greatly misunderstood concerning amputation of the cervix I find about twelve or fifteen cases of laceration every year, in which the injury has been so extensive that it would be bad surgery not to amputate It should be only thought of in the case of women who are pretty well advanced in life" His objections have always been directed "against the removal of an apparently elongated cervix, when the real condition has been not an elongation, but a prolapse" Now, my friend Emmet has not considered the subject on this point—see my paper on Physiological Lengthening of the Cervix Uteri, etc I have been present at operations for laceration of the cervix uteri which I must confess I should never have considered of this nature Emmet himself does not perform the operation as often as he has done The very proposition to repair a laceration for rent by delivery of the child, has won many and many a professional gentleman to consider that was the correct and true and proper treatment My own experience with the views I entertain and from long experience and a large practice is that this is only justifiable in a few cases The frequency of the operation is to be condemned The operation will, I believe, in a few years, not be performed as many times as it has, and possibly in only a few cases It will be relegated to the same tomb with the posterior division of the cervix, or the bilateral incision of the cervix uteri, for they are things of a day Any new operation on the cervix uteri must run the gauntlet and be tested by time But, alas! these important and vital organs have been cut and sewed up so much and in such great numbers, that it is, from the injury it has undergone, not to be considered an organ that conservatism is required, but must always be treated surgically, as one author has said, "It is only to be treated surgically"

These replies are sufficient to prove that the question could not have been put to greater advantage, for it simply forces one to the conclusion that they are nearly all agreed that when the operation is performed early and properly, in well selected cases, it will, and in many cases entirely, prevent such uterine and pelvic disease as usually arises therefrom

Q 6 Do you believe that Emmet's operation is absolutely necessary in certain cases? If so, specify the class of cases

Duncan answers "No" Thomas says Yes, in all of great lacerations Byford gives no answer

Engelmann It is necessary in all cases in which symptoms—which can not be allayed—depend upon the laceration

Jackson Yes Cases in which the laceration extends beyond the crown of the cervix so as to permit eversion of the lining membrane In laceration of less extent after childbearing has ceased, in order to lessen danger of malignant disease

E Wilson Yes, where the rent is more than a quarter of an inch in length and when hypertrophy of the cervix exists with ectropion C M Wilson Yes, if the rent is extensive, and if the symptoms, local or reflex, are of a serious nature

Nash Yes, especially those accompanied by eversion and endometritis, which if cured or improved invariably return unless the operation is made, those accompanied by menorrhagia, displacements, etc It is especially useful in a hyperplastic condition of the organ, favoring complete involution

Lyman In case of reflex disorder, intense local congestion of womb and ovaries, leucorrhœa and general nervous derangement Sutton Yes, in cases where subinvolution and cervical disease exists

Mundé Yes, absolutely necessary in large gaping rents with everted and eroded lips, and freely secreting cervical canal, in subinvolution and areolar hyperplasia, with villous degeneration of endometrium and menorrhagia, dependent on the laceration, in habitual abortion and conditions given under question 3 Van de Warker Yes, when it results in conditions stated in question 3, and when in advanced age it prevents senile involution Prince Yes, when the conditions in question 3 exist

Johnson I do In cases where the above-named (question 3) and other pathological conditions follow its occurrence, and are not curable by other means. If local treatment would cure, don't operate

Hunter When there is much hypertrophied and cicatricial tissue

King Yes In any case where disease of the pelvic organs or tissue is directly traceable to this as a cause

Palmer Absolutely necessary, in most cases of deep seated, bilateral or stellate lacerations, even before secondary changes have taken place Also, in less marked laceration, if these changes are present as results

Goodell Cases of ectropion, cases of tender and neuralgic cicatrix, cases of hypertrophy, cases in which cancer is hereditary in the family

Mann In cases where symptoms are serious enough to demand it, and where there is hereditary cancer

W H Taylor In extensive lacerations Baker also says Yes In extensive laceration, with eversion and cystic degeneration

Jenks Yes In cases where local and constitutional symptoms indicate uterine or pelvic disorder, and examination reveals the existence of cicatricial tissue, with more or less connecting tissue growth, the neck enlarged, and particularly if the nabothian glands are notably developed

Reamy Whenever the laceration has left marked deformity, as ectropion, or when hard cicatricial tissue is in the field of repair, whether the tissue causes pain or reflex irritation or not, I consider the removal of it necessary in order to guard against cancer

Harvey In all cases where uterine symptoms cause the woman to consult a physician

Murphy It is necessary in deep lacerations of the cervix uteri, and ought to be performed for the reasons above stated

Byrne Only in cases where the injury has been considerable, and where eversion of the cervical membrane exists, or dense cicatricial tissue occupies the seat of injury

Lusk Yes In prolonged cervical catarrh, in hæmorrhage from uterine cavity, and in reflex neuralgias, in constant backache, and where walking without unusual fatigue is impossible

Chrobak Absolutely necessary In some cases of extensive ectropion and severe symptoms

Howard I have fully given my views under this head in the report I send you

Wylie Yes, when deep seated glands and follicles are diseased to remove them operation is necessary, and I think Emmet's the best

J E Taylor This has been answered above

The sum total to all replies received on this inquiry, is that the operation should be carefully and perfectly performed

1 When pathological changes exist which depend upon the laceration, and which cannot be disposed of by other treatment

2 When the laceration is deep, bilateral or stellate, with a history of cancer, even before secondary changes occur

3 When in advanced age it prevents senile involution

4 Where subinvolution and cervical disease exists

5 Where there are large gaping rents

6 When there is villous degeneration of endo*metrium*

7 In menorrhagia

8 In habitual abortion

9 To lessen the danger of cancer after child-bearing period

10 Where there is cicatricial tissue in the rents, causing reflex symptoms

Q 7 Do you believe that every lacerated (not fissured) cervix will cause, eventually, uterine and pelvic disease?

Thomas, Engelmann, Johnson, Prince, King, Duncan, W H Taylor, Jenks, Byrne, Lusk and Howard give a simple and decided negative

Jackson, Hunter, Palmer and Baker answer Not necessarily

Sutton and Harvey answer simply affirmatively E Wilson and C M Wilson As a rule Byford Not always, but often

Nash The great majority Some may escape by reason of unimpaired uterine ligaments, but very few Lyman Perhaps not universally, but in the great majority of cases

Mundé No Many a case, even of large laceration, will heal over and never produce any symptom whatever Van de Warker Only when of the extent named in 3d question

Goodell I do not think that every tear will, but I think that the great majority do cause pelvic troubles of some kind

Mann No, by no means Many cases seem to suffer very little from it, or not at all

Reamy No Anterior laceration frequently heals without operation, leaving scarcely a trace, and in other forms of moderate degree no evil is manifest

Murphy No, because, as above stated, pelvic and uterine disease usually accompany a lacerated cervix

Chrobak Comparatively few lacerations produce symptoms so severe as to render the operation absolutely necessary

Wylie No If healthy, even when extensive may do no harm

J E Taylor By no means Too many cases have been seen to adopt that view

This seems positive evidence that we have exceptions, and that all lacerations do not contribute to uterine and pelvic pathology Those who have observed the greatest number of cases, and who have practiced longest and most skilfully in this department, are found among those who believe that not every laceration produces diseases of the uterus and its surroundings

Q 8 If not, state approximately how many such cases you have observed?

Byford, Hunter, Goodell, Lusk and Chrobak give no answer, and C M Wilson and Sutton answer "None" Duncan says Never observed (except immediately—not eventually)

Thomas says Impossible to do so Lyman; Very doubtful, certainly a small number Mann "cannot tell—quite a number" Wm H Taylor "cannot answer definitely" Baker Cannot state number of such cases which have been observed. Jenks Unable to say how many I have seen hundreds Reamy Quite a number, cannot say how many Howard I can give no accurate idea of the number of cases I have seen not requiring operation, but they are not infrequent Van de Warker A very large number in which I did not believe the operation called for

Engelmann says I have seen quite a number of such cases, but by far the minority in cases of laceration Byrne Very many—perhaps hundreds Jackson In many cases could not believe the symptoms were dependent upon the laceration Murphy: About 50 E Wilson gives "six" Nash About 40 cases Wylie About 600 times Mundé One hundred or more I have no positive notes on this particular point, but have often declined to operate. Johnson says I have seen many cases where no symptoms were complained of Prince Have not kept statistics, but I have seen numerous lacerations unattended with inconvenience King Not many I believe that 95 per cent of real laceration will, ultimately, cause disease of some kind Palmer But such results (mentioned before) are so constant as to form the rule The proportion upon results is very small and exceptional Harvey If upon examination of a case laceration is found, I know of no means of explaining it away as a factor in the etiology J E Taylor Answered above

This is one of the most important questions, and yet one which has been replied to very unsatisfactorily A certain degree of uncertainty is manifest;

most of my correspondents guess at it, only one or two make exact statements Yet it must be considered that in the practice of nearly every one, numerous cases have occurred, in which a lacerated cervix excited none of the affections that usually are said to arise therefrom

Q 9 State approximately or exactly, if you can, how many times you have performed the operation?

To know about how many operations have been made by those who favored me with an answer, would give, I thought, weight and strength to their opinion Unfortunately, some who have had a very large experience, and who are known to have operated hundreds of times, can not, even approximately, state the number of their operations Dr Emmet refers me to his last edition, and there I find that up to the time of its publication, he has apparently operated over 600 times It is safe to presume that Dr Gaillard Thomas has probably performed the operation an equal number of times Lyman, of Boston, simply states that he operated on a considerable number Byford, of Chicago, and Taylor, of Cincinnati, do not respond to this question at all Not willing to be accused of exaggeration, I have rated the combined experience (although I am satisfied it is too low an estimate) of—

Emmet, Thomas, Lyman, Byford and W H Taylor, of Cincinnati,		as comprising about	1500	Cases
G T Engelmann	about	(40-50)	45	Cases
A Reeves Jackson	"		200	"
Ellwood Wilson		exactly	128	"
C M Wilson		"	12	"
Herbert M Nash	"		22	"
R S Sutton	"		100	"
Paul F Munde	"		200	"
Ely Van DeWarker	"		120	"
Jos Taber Johnson	"		30	"
James B Hunter		at least	200	"
David Prince	"	'6-8)	7	"
Willis P King		exactly	7	"
C D Palmer	"	(35-40)	37	"
Wm Goodell		exactly	263	"
M D Mann	"		90	"
W H Baker	"		400	"
E W Jenks	"		200	"
Thad Reamy		exactly	324	"
T B Harvey	"		200	"
P J Murphy	"		50	"
J Byrne	"		200	"
W T Lusk	"		300	"
Chrobak	"		10	"
W T Howard	"		100	"
A H F Barbour			0	"
J Mathews Duncan			0	"
W Gill Wylie	"		200	"
			4,945	

Here we have then, in condensed form, the experience of 32 operators, nearly all of whom have a reputation throughout the country, some over the whole civilized world, men who are known to be conscientious, active and zealous workers in the profession, all of which, I think, will go far to substantiate the conclusions given at the end of this paper

Q 9a How often for the restoration of the cervix simply?

To this question Thomas Byford, Mundé, Goodell, Lusk, I E Taylor and Chrobak give no answer

Engelmann, Nash, Sutton, Van de Warker, Prince, King and Duncan answer "Never"

Jackson answers 20 or 30 times E Wilson About 20 per cent C M Wilson 1 time Lyman Often, as preventive of impending trouble Johnson Never for the sake of operating, only for the cure of symptoms

Hunter About 25 per cent Palmer To restore cervix before pathological changes have occurred—3 times

Howard "cannot say" Mann "cannot separate causes" Wm H Taylor "cannot answer definitely"

Baker Can not divide them without weeks of work in going over records of cases Jenks Can recall to mind but one, and that was a month after childbirth In this instance there was almost constant hemorrhage from laceration of circular artery Reamy Never, because have always had in view this and its present and ultimate consequences Harvey In about one-fourth the cases Byrne Can not say, but not a majority Wylie Rarely, never lately

This question I asked for the purpose of ascertaining how many there are who believe in restoring a lacerated os, before pathological changes have occurred, and about how many times the operation has been performed for that purpose alone

Q 9b How often for the relief of pathological changes and reflex disturbances depending thereon?

Thomas, Byford, Goodell Reamy, Murphy and Chrobak give no answer

Engelmann, Sutton, Van de Warker, Prince and Lusk answer "always"

Jackson says All the others (see *9a*) E Wilson says About 80 per cent C M Wilson 11 times Nash Always In five cases operation for lacerated perineum was done at same sitting Lyman More often for this class Mundé Much more ofter than for question *9a* Johnson About 30 times Hunter About 75 per cent King Seven Palmer Some 35 times Mann "cannot separate causes"

Duncan answers, "Never" Wm H Taylor "cannot answer definitely" Baker Can not divide them without weeks of work in going over records of cases Jenks Have always operated on account of pathological changes in the uterus, or reflex disturbances depending thereon Harvey Probably one hundred and fifty Byrne In most cases operated upon Howard "cannot say" Wylie About 200 I E Taylor Not by closure, but by amputation as above referred to

This, of course, includes all the other operations, with the exception of those that may be contained among those who did not answer questions *9* and *9a*

Dr Emmet and Dr Thomas have confessed, on more than one occasion, that to day they do not operate as frequently as formerly, because experience has taught them that oftentimes the operation had been performed unnecessarily (of Byford, and Lyman, and Taylor, Cincinnati, I have no knowledge regarding this point), but whether by that they mean to say that they operated in cases of laceration without complication, as well as in cases in which the complications were looked upon as following a torn cervix, can only be conjectured For this reason I wish they had answered at least question *9a* Since I have estimated the number of their operations so low already, I will permit them to stand, and count them with those cases in which the operation was performed only for the relief of pathological changes, local as well as general, and if afterwards it is discovered that some of them were performed in cases of uncomplicated lacerations, let them be counted with those for which they were not credited

Q 10 What have been your immediate results respecting union and relief?

Thomas says Almost uniform success Engelmann First intention Jackson Only know of four cases of non union Relief of symptoms did not always follow the other cases Byford gives no answer E Wilson says Always good, non union in only one case Never have had serious results follow C M Wilson Good Nash They have all been successful in union, and were relieved of the symptoms for which the operation was done One invalid eight years could not walk 200 yards, relief entire Lyman Have been very rarely obliged to repeat the operation The relief has in every instance been satisfactory Sutton answers In my early cases I had union of both sides fail occasionally In the last two years failure to make union has occurred only once Mundé About 92 per cent union, certainly 75 per cent relief from symptoms for which operation was done Success depends on following proper rational indications Van de Warker Union has never failed Sometimes have been disappointed in general results Johnson Good I had one case of acute cellulitis follow, and in one case sutures all tore out I operated again and cured the case so far as I know Hunter says Very satisfactory Non-union rare exception Relief comes later, six months to a year Prince Benefit King Had perfect union in all, and all gave relief Palmer In the great majority of cases the immediate results have been satisfactory as to union and local relief Goodell I have very rarely failed to secure union, but I have sometimes failed to get relief Mann Have only failed of union four times None lately Relief in at least 95 per cent of cases Duncan gives no answer Wm H Taylor says Cannot answer definitely Baker Almost universally good Union by first intention in nearly every case, and no complication save pelvic cellulitis in one case, death by septo pyæmia in one, and phlebitis in one Jenks Have usually had union, but not immediate relief look for the latter in about three months I have been unable to follow up all of my cases Have failed to obtain union in five cases I desire to add as a partial answer, that I deem it of great importance to secure union in plastic operation about the generative organs of women, that a condition of health must be attained This is done in many cases only by local and constitutional treatment Reamy says Union in almost every case Harvey Good as to union in most cases, failure in about 5 per cent Good in most all where all cicatricial tissue was cut away Not good when this was not done Murphy Union by first intention has followed in almost all cases Byrne Almost universally successful Tusk Failure to unite has occurred perhaps a half dozen times Amount of relief variable—often complete, and always sufficient to repay for the operation Chrobak Absolute first intention in every case, and perfect success Howard After I gained experience almost always good Wylie Never failed to get union and almost always effected a cure

From this we learn that, as a rule, good will follow the operation, not always immediately, yet oftentimes in the course of three to six months thereafter, that union but rarely fails, and that it is more apt to be obtained when the cicatricial tissue has been well taken out, or the parts have been effectually treated for the relief of certain diseased conditions prior to the operation The answers to this question also furnish evidence that the operation is accompanied by some danger, since in one instance death occurred from septo pyæmia, and in one from phlebitis

Q 11 What have been your remote results respecting union, relief and sterility?

Thomas answers Very generally good, and Engelmann Excellent, conception rapidly follows Jackson says In a few cases (perhaps 10) sterility lasting several years seem to have been cured by the operation

E Wilson says Excellent, have delivered 12 women on whom I had previously operated, one twice Recurrence of tear in two cases, and C M Wilson says Good

Nash I am not able to report positively on this matter 10 of my patients in the childbearing age are now under observation as to the bearing of the question Lyman Impossible to say, as a large number have been hospital cases Sutton I have not been able to follow many of the cases Some have become pregnant

Mundé 25 per cent of cases under my knowledge conceived after the operation, undoubtedly many more did so but were not reported

Van de Warker And large number of cases relieved of sterility, and Johnson My remote results have been good I believe it cures sterility instead of producing it

Hunter says Highly satisfactory, Prince, "can't say", Palmer Largely, very beneficial Wm H Taylor "can not state definitely", Jenks I am unable to answer, except as above, as the patients have been from various parts of the country Chrobak "cannot answer", and Howard says I have not followed up many cases, as they were generally from a distance, and I have long curtailed obstetric practice

King says that Two out of seven have borne children, one of them two since the operation

Goodell On the whole I think that operation does not cause unfruitfulness, as I used to think, and the remote results have been better than the immediate ones.

Mann Sterility cured in small number, but have not been able to follow cases Baker Good in overcoming sterility Reamy Properly done does not cause but often cures sterility Good in large per cent of cases Have had failures as to relief of reflex and other symptoms It is not a "*cure all*" The lesion does not cause all, nor will the operation cure all pelvic disease nor yet all reflex nervous symptoms

Harvey Very encouraging and successful in recent cases, and where there has not been too great a degree of induration Some failures where the opposite conditions exist

Murphy My observations have been few, theoretically I believe it causes sterility

Byrne In cases of sterility from this cause, conception has usually followed a successful operation

Lusk Good, so far as a check upon tendency to abort

The answers to this question must of necessity be more or less indefinite, from the fact that most of my correspondents devote themselves entirely to gynecology, and receive many patients from different and very distant parts of the country They know not what the remote results have been, in probably the majority of cases, on the other hand, one can easily observe that the answers from those whose practice is more limited, or rather local, are much more definite In general, the replies are favorable respecting relief of spmptoms, cure of sterility or unfruitfulness, as Dr Wm Goodell prefers to call it, and will aid considerably in permanently establishing Emmet's operation

Q 12 When, in your opinion, is Emmet's operation contra indicated?

Thomas answers In cases of subacute pelvic peritonitis and cellulitis which may be excited into acuity during pregnancy, and after the menopause if no eversion and hypertrophy exists

Engelman says Acute and subacute inflammation or exacerbation of chronic trouble Jackson When there are present evidences of pelvic inflammation

E Wilson Where peri uterine adhesions exist, and the general health of the patient militates against the operation C M Wilson In cases where other surgical procedures are contra indicated, and where the uterus is immobile

Nash In active inflammation of the uterus and its surroundings I have almost invariably used local treatment to relieve all active disease before operating

Lyman When there is neither eversion, local congestion or reflex disturbance In such cases the only excuse for it would be the possibility of growth, and of this the patient should decide for herself

Sutton When the ovaries or tubes are diseased, when the uterus is very irritable, when the laceration is not accompanied by symptoms of uterine disease

Mundé When not indicated, *i e*, not the rent *eo ipso*, but the symptoms produced by the rent, call for the operation Acute and chronic pelvic inflammation

Van de Warker In lymphadenitis in pelvic inflammation and its products, phlegmon and ulcers

Johnson When no sympsoms exist which demand it, and where any cellulitis exists

Hunter answers Chiefly in cases of acute cellulitis, and Prince Never, only it may not always be necessary

King says When reflex troubles are traceable to other causes, with manifest hydro or pyo salpinx, it should not be done That is, Emmet's operation is contra indicated, when Tait's operation is manifestly indicated

Palmer When there is co-existant or inter current chronic peri or para metritis The granular condition may forbid, but the para metritic complication is the chief contra indication

Goodell In fissures of no great magnitude, and in all cases in which the ectropion is slight, and yields to local treatment

Mann When pelvic cellulitis and peritonitis are not well cured, or cancer is developed

Duncan says Almost always, and Wm H Taylor Not needed in limited laceration

Baker When there is any acute or subacute inflammatory action of cellular tissue or peritoneum around the pelvis

Jenks Where there is no ectropion few or no cicatrices, no particular enlargement of the uterus, no Nabothian bodies apparent Also where there are no symptoms that can be considered of uterine origin

Reamy All cases where laceration is slight, and has been followed by no symptoms referable to it—during pregnancy, during presence of acute or sub acute metritis, peritonitis or pelvic cellulitis, cancer of neck or body of uterus When patient is suffering of pulmonary consumption, or any other fatal malady

Harvey I can not see why it should not be tried in all cases where laceration or fissures exist, provided epithelioma has not invaded the parts so deeply that we can not hope for union

Murphy It is contra indicated when the lacerated cervix is accompanied by uterine and pelvic disease, and ought not to be performed unless in the graver lesions of the cervix

Byrne In chronic pelvic cellulitis anæmia or other depraved state of the system

Chrobak says The operation is more frequently performed than necessary, it is only indicated, with the exception of general indications, when acute inflammation exists

Howard You will find this answered in my report (See his report)

Wylie When mucous membrane is healthy Before any serious complications such as endometritis, parametritis and perimetritis are cured, when uterus is fixed and *not freely movable*

I E Taylor It is contra indicated in a large number of cases, and only necessary in the class of cases I have referred to as above

These answers may be summed up as follows

1 In acute and sub acute inflammations
2 In pelvic cellulitis
3 In pelvic peritonitis

6. When uterus is very irritable.
7. Never the rent, eo ipso.
8. Pregnancy.
9. After menopause, if no eversion or hypertrophy exist.
10. Manifest hydro or pyo salpinx.
11. Where there is no ectropion.
12. Where there are no Nabothian bodies apparent.
13. When there are no symptoms of uterine origin.
14. Not needed in limited lacerations, anemia or fissures.
15. When local treatment gives relief.
16. When peri uterine adhesions exist.
17. When uterus is immobile.
18. When there is neither eversion, local congestion nor reflex disturbance.
19. When there is cancer of neck or body of the uterus.
20. When patient is suffering of pulmonary consumption or other fatal malady.

The summing up and condensing of all the answers to these questions has been a laborious yet interesting work. I might here abandon my inquiry and rest content with what can be learned from it, and leave my audience, as well as those who may chance to read it in the future, to draw their own inferences, but I feel that my effort to create more harmony will have been in vain, if, after studying the different views of the various operators, I should not attempt to answer the question that has called forth this essay. I do not flatter myself that my views of this subject, gained from the above, will agree with all of you, nor with all those who will read it hereafter, but I present them with the hope that they may aid to clear the way to a better understanding. The above inquiries certainly furnish abundant proof of a great difference of opinion among gynecologists as to when it would and when it would not be proper to perform the operation. They may be divided into three classes: those who advocate operative interference in every lacerated cervix, those who do not endorse the operation at all, and those who deem it a necessity in some "well selected cases" only.

That the operation is too often performed, that cases are operated upon in which no indications for it exist, that as a consequence the results looked for are not obtained, that the patients, so far from being relieved, are subjected unnecessarily to procedures not free from danger, and are occasionally even followed by unfavorable results, rendering the patient worse instead of better, is the opinion of many. *The abuse, not the use of the operation, has done the mischief.* In the heat of debate many will defend the grounds they have taken, and fortify their position by apparently plausible arguments. But the quiet looker-on—the unprejudiced and diligent student of this question—will come to the conclusion that the charges made are only too true. The accompanying tabulated record, as well as Dr. Emmet's letter, will testify to this statement, and I do believe that many of the gentlemen who have performed this operation are willing to admit the same.

Like any other new remedy, this operation has been resorted to because of its evident utility, and too much has been expected from it. That, however, might have been looked for from its first announcement. The same fate has followed every newly invented operation. But while this is no reason that the operation should be abandoned, as some, especially from abroad, would have us to do, there is certainly to-day no longer any excuse for performing this operation for every laceration we find. We all have heard the remark, and probably have made it ourselves, I know I have, that if a lacerated cervix is the cause of all the ills text-books and authors attribute to it, then every rent in that portion of the womb ought to be sewed up.

Here it is that we must pause and reflect upon the experience of others as well as our own, and when we do so, one is compelled to admit that *it is not true that every tear in the cervix is productive of evil, and that it is not good practice to stitch up every os, simply and solely because it sustains a slit, nor is it fair to assume that because of certain diseased conditions coexisting in, around, or near the cervix or uterus and its appendages, an operation is necessary to a cure.*

To be better understood, I have drawn two diagrams to illustrate the various degrees of lacerations as we observe them in practice. Figs. 1 and 2 almost explain themselves. Fissures are, indeed, lacerations—lacerations which, in my opinion, have been more or less extensive, but have failed to heal perfectly, leaving a depression or gutter in the cervical canal, to which the name fissure has been applied.

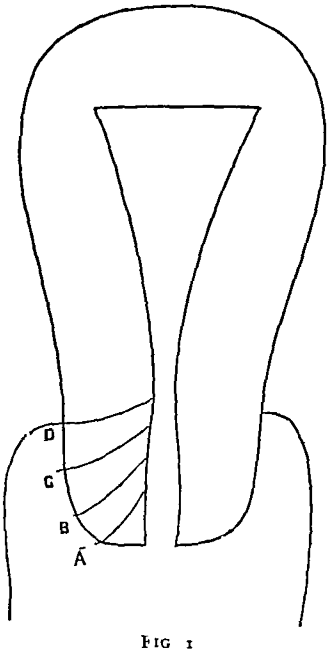

FIG. 1.

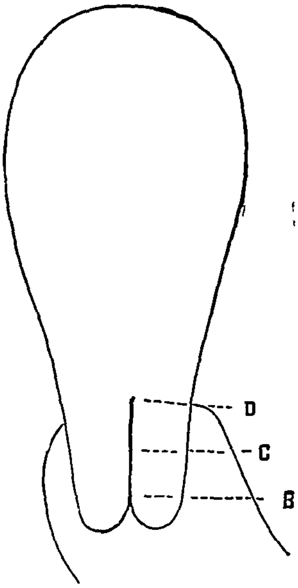

FIG. 2.

a (Fig. 1) represents my idea of a fissure. From *a* to *b* constitutes a laceration of the first, from *b* to *c* a laceration of the second, and *c* to *d* a laceration of the third degree. Lacerations extending through and beyond the cervico-vaginal junction, if not amounting to a rupture of the uterus, may be considered lacerations of the fourth degree.

The following are my conclusions, drawn from the above tabulated record, from text-books, from the numerous articles referred to, and my own clinical experience, extending over a period of seven years as assistant of Prof. C. D. Palmer's Clinic, at the Medical College of Ohio.

1. It is evident that *the operation has been performed unnecessarily for symptoms similar to but other than*

those arising from lacerations of the cervix. Further, that *it has been done imperfectly, even without preliminary treatment, in many more,* and *the failure to give relief,* as reported by several, *is due to these two causes.*

2. That from our present knowledge we cannot, at this time, arrive at any definite conclusion, from the fact that many of the so called consequences of lacerations of the cervix uteri are not settled beyond doubt.

3. That every one engaged in this department should carefully select his cases, and try every known means to give relief before recourse is had to an operation.

4. The operation should never be performed *eo ipso* in cases of simple fissures or lacerations of first and second degree.

5. In cases of eversion and disease of the cervical or corporeal cavity, or both, although attended by hyperplasia and displacement, it has been observed that all the symptoms abated and the parts returned to their natural condition, and that no laceration was discoverable after alleviative measures were instituted first, which alone caused the parts to return to a normal condition.

6. That there are some cases of extensive lacerations of cervix that seldom give rise to any inconvenience, and that, therefore, an operation should be deferred until symptoms arise that will call for its performance.

7. The operation, although indicated, should never be performed until, by preparatory treatment, the parts have been brought into a healthy condition.

8. Near, and during, the climacteric period the operation should be postponed as long as possible, and the patient not exposed to any risks, since in many cases all the symptoms subside under proper treatment, and never return on account of senile involution.

9. The operation is justifiable in cases of lacerations of the third and fourth degree, without complications, if there is a history of malignant disease in the family.

10. The operation may be performed with perfect propriety in young women, as a preventive, if the laceration is bilateral and extends up to the cervico vaginal junction, or beyond it, even though there are no pathological changes; indeed, it seems to be the duty of every one, who observes a lesion to that extent, to urge the operation.

11. The operation is justifiable in any degree of laceration, and in rare instances even in fissures, when there exists cicatricial tissues, productive of reflex disturbances, annoying in character, and not tractable to any other treatment.

12. The operation is absolutely indicated in all extensive tears of the os, in which the cervix is everted, its mucous membrane and Nabothian follicles diseased, and especially if there be granular or cystic degeneration present, provided the parts have been restored to a healthy condition by palliative treatment.

ON REPEATED DOSES OF CASTOR OIL, ESPECIALLY IN CERTAIN SKIN DISEASES IN CHILDREN[1]

BY L. DUNCAN BULKLEY, A.M., M.D.,

OF NEW YORK.

Castor oil is such a common and well known remedy that it would seem that but little could be written with regard to its employment in medicine. Everyone is thoroughly acquainted with its characters, dosage and use, and even the laity appreciate its value and employ it freely without medical advice. But, as far as I can learn, its use is confined to the administration of single doses, now and again, as necessity demands to remove offending contents of the gastro intestinal tract; with the single exception, perhaps, of the well-known mode of its employment in emulsion, in frequent doses, for the relief of diarrhœa and dysentery.

In the present communication, however, I wish to call attention to the value of castor oil in certain cases, in which frequent and repeated doses of some size, and continued even for a considerable period, will produce effects difficult to obtain by other means. I will first give in brief the notes of a case, that of a child, in whom its virtues were strikingly exhibited, and which especially confirmed me in the practice now advocated.

The child, aged six years and a half, was brought to me suffering from chronic urticaria, which had existed off and on for some little time, and had resisted good treatment at the hands of others. The child was fairly developed, but of an earthy complexion, was restless, peevish, and complained continually of great fatigue. She had previously taken as a tonic an iron mixture, and also mixture of rhubarb and soda, but without benefit to her health; she had recently been in the South, and had contracted malaria which quinine held in check with difficulty. She was found to be the subject of urticaria, the wheals developing rapidly at any time of the day, and from no especial cause. When seen there was not very much of urticarial element present, but there was more or less of the papillary eruption left after the disappearance of the former lesions, constituting the disease known as urticaria papulosa. Her pulse stood at 94, of fair strength, the tongue was moderately clean. For some time previously she had complained of pain in the right abdominal region, and would call attention to it frequently. On percussion of the abdomen the right iliac region was found to present very considerable dulness, extending well up to the liver, and somewhat into the transverse colon; there was no special dullness on the left side. She had complained of diarrhœa, the movements, however, were ineffective, and often more or less lumpy.

She was ordered to take a teaspoonful of castor oil every night, and was also given an emulsion of castor oil with gum arabic and sugar and a little opium, to check excessive action. Twelve days later she was brought to the office having taken a teaspoonful of castor oil every night in the intervening time. This had never acted more than three times daily, and generally not more than once or twice The diarrhœa had been checked in two days, but she still complained of pain in the abdomen, sometimes in the left side, with which she had had two attacks of crying She looked very much better in general appearance, with less of an earthy color, and her appetite, which before had failed entirely, was now good On percussion the abdominal dullness was decidedly less, but still marked, the stools had contained more or less of lumps with each movement The administration of the oil every night was continued, and two grains of quinine were ordered to be taken before each meal About a week later she was again seen, and appeared to be still better in health, the pulse was 80, and the tongue clean The oil had been increased to a teaspoonful and a half each night, and lumps had ceased to appear in the stools, which presented only healthy fæcal matter The pain had ceased entirely in the abdomen, but there was now more general dulness over the entire abdominal region It was then attempted to administer again to her an iron mixture, with the continuance of the oil, but this shortly disagreed, causing her to sleep badly and to be restless and irritable, and it was discontinued, and an alkaline and bitter tonic given in its place About one month after the commencement of the castor oil it was recorded that she looked remarkably well, fat and round in the face, had lost the pale earthy look, and had gained two pounds and a half in flesh, the abdomen was resonant all over

---

[1] Read in the Section on Diseases of Children at the Thirty Sixth Annual Meeting of the American Medical Association.

The castor oil was still continued in moderate doses, producing one or two quite healthy movements Shortly after this the oil was omitted for a few nights, contrary to directions, and she began to be again troubled in her sleep, and felt poorly, and the urticaria which had disappeared very shortly after beginning the oil, returned in considerable degree The abdomen was found to be again dull on the right side, and the castor oil was returned to, with the result of producing shortly a resonant abdomen She was then given a mixture containing lactopeptine after each meal, which had the effect of inducing regular healthy action of the bowels The urticaria had ceased with the last administration of castor oil, and the child remained afterward in much better health, but on another occasion somewhat later the abdominal indigestion returned, and the castor oil was again returned to with good effects

In this case the little patient took the castor oil continuously for over one month, and for shorter periods on three other occasions In a number of cases of infantile eczema, even where there was not the evidence of obstructed bowel excretion, I have administered castor oil as in the preceding case with great advantage, in doses varying according to the age of the patient and the necessities of the case, never, however, so as to produce purgation, but only to excite a somewhat increased and healthy discharge from the intestinal canal

In one case, that of a boy aged about 8 years, the impetiginous eczema which had cropped out from time to time upon the face and scalp, yielded most happily to this course of treatment, but, as happens so frequently in public practice, the neglect of treatment for a period, together with bad dietary and hygienic surroundings, necessitated its use on several occasions This child had also ulceration of the cornea, and at several visits the mother would remark that this ulceration, which had resisted local treatment at the hands of oculists, yielded in a remarkable manner each time when the oil was administered

Acting on the suggestion mentioned in the last case, I employed this treatment by repeated doses of castor oil with very great advantage in a case of acne rosacea, complicated with persistent and rebellious corneal ulcerations, in brief as follows

Mrs R , aged 26, had had acne simplex and rosacea for several years, connected with and dependent upon great constipation, uterine disorder, and much general debility For many years she had been troubled with the eyes, having recurring ulceration of the cornea and much conjunctivitis very frequently For this she had been under skilled treatment, but never with anything more than a temporary improvement Time and again during the treatment of her acne rosacea she came with the eyes almost useless, and suffering greatly from them This condition was found to vary considerably with the state of her digestive organs and with the eruption upon her face, and several times the eyes ceased to give trouble for quite a period when the other symptoms improved Soon after the occurrence of the case just mentioned, she had another severe attack of ulceration of the cornea and conjunctival irritation She was then placed upon castor oil, taken every night in doses of from two to four teaspoonfuls This was taken continuously for something over a month, and the record was made that it had helped her general condition greatly, and her eyes in particular The eruption upon her face was better than it had been for a very long time Castor oil was still continued in connection with tonics, which before had proved inefficacious alone, and nearly a month subsequently it was noted that her general health was better than it had been for a long time, and that she had as yet had no return of the difficulty with the eyes She was seen subsequently, after an interval of about a year, and stated that from time to time she had returned to the castor oil treatment immediately that the eyes gave any indication of inflammation, and always with the happiest effect, a few doses sufficed to check this trouble, which before had invariably run on to producing very serious inconvenience and distress

Castor oil is also often of value in other conditions not associated with disease of the skin, as in the following rather striking case of chronic and recurrent tonsillitis

L B , a very bright, rather precocious, child of 7 years, came under my care December 14, 1883 He began to have attacks of throat trouble when but one year old, the tonsils becoming swollen and covered with small yellow points, as in ordinary follicular tonsillitis The attacks lasted one week, during which time he was generally in bed most of the time, and from that period until the date of his visit at 7 years of age, he had had recurrences of this throat inflammation every month, except when away from home in the summer, with very few exceptions, occasionally missing a month or two under active treatment With these attacks he would always have pain in the stomach and nausea, and latterly very great pain in the head The attacks were often preceded by slight chills, and before their occurrence the movements from the bowels would become lighter in color, and clay-like, up to the time of the attack Between the attacks the bowels were apt to be constipated, the sleep was bad and restless During the attacks the urine would become very high-colored, and afterward would throw down abundant deposits The last attack had begun two weeks before his visit, he having been out of bed only six days when brought for treatment, from his home in New York When first seen, the tonsils were found to be enlarged and covered with small cicatrices, and *presented a few very small yellow points* On percussion over the abdomen the liver was found to be considerably enlarged, protruding plainly below the line of the ribs The spleen was two or three times its natural size, and the abdomen appeared full and rather tense with gas, but considerable dulness was discovered on deep percussion In several places there was much tenderness on deep pressure

He was directed to take two teaspoonfuls of castor oil every night, and no other treatment Three days later it was recorded that the castor oil had agreed perfectly, and had acted gently upon the bowels, producing about one movement daily, which was a little loose, the first movements which occurred being lumpy He then returned to his home in a somewhat malarious district, continuing the oil as before every night, but in somewhat increased doses One month from the beginning of the previous attack, it was thought that he had a slight chill, but he did not take to bed as before The next day there was some little fever in the afternoon, and nausea at night, with a little soreness of the throat, which, however, passed off the next day He had omitted a dose or two of the oil just previous to this slight attack The movements had been somewhat light colored, but better than previously He was brought to the city from some two hundred miles distance, the second day after the slight chill just mentioned, that is, during the period when he should have had his attack The throat was then seen to be but little red, there was no ulceration, and he complained of no soreness He was then given a rhubarb and soda mixture in place of the castor oil, but this failed to be as efficacious, and two weeks after the last note his throat again became a little sore, although there was nothing to be seen The movements were again very light colored The castor oil was then returned to at night, and a mixture of chlorate of potash and iron was given for the immediate relief of the threatened sore throat The next day or two he had a little fever, but was able to come to the office, and shortly after he went to a country place quite free from malaria, but did not stay longer than a week or so He then returned to his home, continued the castor oil every night, and taking also the syrup of the lactophosphate of lime after each meal On March 22d, it was recorded that he had taken the castor oil continuously, two teaspoonfuls each night, and that he had not had any further difficulty with the throat, it being now full eight weeks since there had been any trouble at all The movements were still inclined to be rather light colored, but although living at home he remained entirely free from his throat disease until June 6th He then had a slight attack of fever with a little headache and sore throat, which, however, did not confine him to bed, there being no yellow points on the tonsils as before He had become rather careless in diet, and it was learned that the location and house in which he lived were in a bad sanitary condition

Other cases could be cited in children up to the age of ten years in which the castor oil was administered upon this plan for periods varying from two to four weeks or more, with the result of removing *abdominal dulness, and with it debility and a train of* unpleasant symptoms One particular case may be alluded to, in which a little child, three years and a half old, who had eczema in infancy and urticaria subsequently, was very greatly improved in health by the administration of the oil for a period of over five weeks During this time her appetite, which had failed entirely, returned with vigor She gained in flesh and color, and at the end of the period mentioned, her condition was as far different from that at first as could be imagined, greater than one often sees produced by any course of medication Various tonics previously given had failed to be of much benefit

The cases which I have here cited, together with a number of others, show that castor oil may be taken with advantage repeatedly for a considerable period of time In the boy with the sore throat this treatment was carried out for a period of almost six months, with few intermissions, he repeatedly taking it for a month or more without intermission

In regard to the mode of action of the oil, in these cases it acts unquestionably as a stimulant to the abdominal organs, the color and character of the movements from the bowels being the indication with regard to its use In those cases, which I believe to be not infrequent, where there is intestinal torpor followed by greater or less accumulation of fæces in the large intestine at either side or throughout its entire length, this plan of treatment is peculiarly happy and beneficial in its effects The apparently tonic effects following this course of treatment must be attributed largely to the improved absorption and assimilation which take place in the gastro intestinal tract, although it is quite possible that some portion of the oil thus taken acts as a direct nutrient Many cases of skin disease, especially urticaria, are undoubtedly attributable to reflex irritation, having its origin in the intestinal canal, and undoubtedly many cases of tonsillitis have their origin in like manner In repeated instances in my own family have I observed that beginning tonsillitis could be broken up almost immediately by the free administration of castor oil

With regard to the administration of this remedy, which is so often considered nauseous and repulsive, a few words may be added. Specimens of castor oil undoubtedly differ not a little in their qualities, and care should be exercised to secure a sweet, pure and fresh quality of cold compressed castor oil. To adults this drug is undoubtedly repulsive, but in view of the value of the gain which often results from its administration, I have found little difficulty in having a number of adults take it as here described, for a greater or shorter length of time. To children, however, if especial attention is not called to it, the remedy is not as repulsive as to those of older years, and young children are often seen to be very fond of it. In several of my cases in which it was continued for a considerable period of time, the children remarked that they did not find it at all an unpleasant dose to take.

With regard to the mode of administering castor oil, there are very many plans which may be adopted. I may first remark, however, that it is important that the remedy should be taken alone, and not with any other substance which may interfere with its action. I object most decidedly to having spirit, wine, or any such substances added to it, and prefer even that it should not be given in conjunction with orange, milk, coffee, etc. The plan I have usually adopted is as follows: The patient takes a sip of very cold ice water, or a small lump of ice, holding it in the mouth for a moment, and the oil is immediately taken in a single dose from a large spoon. The lips are then quickly and very firmly wiped or rubbed with a towel, and a drink of ice water is taken instantly afterwards. In this way those who have shuddered at the idea of taking the oil have found that it gave them little annoyance, and in this manner it is left free to act in the stomach without the presence of substances which might interfere with its operation.

In conclusion, I would add that in presenting this subject of the repeated administration of castor oil, I do not desire to place too much emphasis upon its value, nor to recommend it as a panacea even for the conditions previously alluded to. In almost all the cases in which I have employed it other remedies have been given either conjointly or from time to time alternated with it, and to them undoubtedly must often be ascribed some measure of the good result obtained. On the other hand, I can affirm that for certain conditions, such as may be learned from the cases cited, I have found no remedy to equal it, and I believe that in these and in many other conditions the prolonged use of repeated doses of castor oil will be found to serve a valuable purpose in our efforts to combat disease.

MEDICAL PROGRESS.

MEDICINE.

Alterations in the Lymphatic Vessels in the Course of Syphilis.—1. The lymphatic system undergoes an almost constant alteration in the course of syphilis. But while the ganglia are quite often modified, the lymph-vessels, on the contrary, are very rarely so.

2. The lymphopathies exist under many conditions, and may be divided into six clinical forms. *a.* In the first place, there is a simple inflammatory lymphangitis consecutive to a specific ulceration, however excited. *b.* A lymphopathy may complicate the infecting chancre, and then it bears the same relation to the lymphatic vessels as the adenopathy consecutive to the syphilitic chancre bears to the lymphatic ganglia. *c.* There is observed a secondary disseminated lymphopathy, which evolves under the sole influence of the diathesis, without being under the dependence of a local manifestation. *d.* In the tertiary stage, certain lymphatics, principally those of the dorsum of the penis, may become sclerosed, and give rise to a special lymphopathy. *e.* A cutaneous manifestation of late hereditary syphilis may be complicated with lymphangitis having a special aspect. *f.* Finally, in acquired, as in hereditary syphilis, there exist alterations of the visceral lymphatics. These alterations, carefully studied from an anatomico-pathological point of view, occasion no characteristic clinical symptom which enables one to diagnose them.

3. Clinically, the different lymphopathies are particularly characterized by the existence of hard, mobile, indolent, aphlegmatic cords, situated exactly upon the anatomical course of the lymphatic vessels. For this the first and the sixth forms described are an exception. The first is an inflammatory lesion, and the sixth a visceral lymphopathy.

4. The treatment should be specific and constitutional. Mercurial frictions are injurious in these cases, because they may irritate the skin or inflame or alter the lymphatic vessels which are predisposed to phlegmasies by the fact of the syphilitic diathesis. In grave cases, subcutaneous injections may be employed which, despite their inconveniences, constitute a most energetic therapeutical measure.—Dr. Paul Salle, *These de Paris*, 1884; *Journ. Cutan. and Vener. Diseases*, July, 1885.

SURGERY.

Injections of Iodoform-Ether in Cold Abscess.—Prof. A. Verneuil had already called attention to this mode of treatment, at one of the meetings of the French Congress of Surgery, and in consequence of a demand on the part of many of his colleagues, gives the details of his mode of procedure in the *Revue de Chirurgie*, for May 10, 1885.

He commenced this mode of treatment in 1883, on the grounds that the contained fluid in cold abscess is of secondary importance to the walls of the abscess itself, and that it is to the latter that therapeutic measures should be directed. The walls comprise two layers, the external fibroid, neoplastic, of irritative origin, but without specificity, and of a nature that, when the irritation has once passed off, is likely to disappear spontaneously like the sac of an aneurism after the absorption of the clots, the internal, on the contrary, contains the cause of the trouble, the tuberculous germ, the parasite. Iodoform seems to be the agent most suitable as a parasiticide in its efficaciousness for this purpose, but being toxic in certain cases and under certain conditions, it was necessary to ascertain how and in what quantity it had best be used First it was necessary to find a vehicle capable of carrying the iodoform to all parts of the abscess, which is so variable in its extent, and so irregular in its walls Ether seems to be the most adapted to this means, on account of its extreme diffusibility, it has other advantages in dissolving iodoform readily, is inexpensive, and has no toxic properties There are certain points, however, to be insisted upon in its management as follows

1 *Evacuation of the pus and consecutive injection* Verneuil uses the aspirators of Dieulafoy or Potain, because they allow an evacuation of almost all the fluid without exercising the slightest pressure upon the sac This, so to speak, spontaneous evacuation is particularly valuable in cases of abscess by congestion that is more or less high up in the abdominal or thoracic cavities, and consequently inaccessible at these points to the action of the hand He uses trocar No 3, prefering it to the needle of the same size, the point of which might wound the walls of the abscess, because an instrument that is too delicate is easily obstructed by the purulent or caseous grumous matter Rather than lacerate the vessels he allows a little pus to remain, and stops its evacuation as soon as the fluid becomes tinged with blood For the same reason he abstains from all washings out, and proceeds immediately to the injections of the iodoform-ether

2 *Quantity and concentration of the liquid injected* At first, in a very large sac, he used more than 100 grammes of ether holding in solution 20 grammes of iodoform, this remained in the sac and gave some serious symptoms of intoxication Since then he has used a solution of 5 per cent, and injected only 100 grammes at most, but usually from 50 to 60 grammes are sufficient In this way the quantity of iodoform liable to absorption is never more than four or five grammes It is prudent to do this, since the chances for absorption can never be calculated in advance, as they depend upon such varying circumstances, as the capacity of the sac, its thickness, permeability, vascularity of its walls, greater or less distension by the injected liquid, etc The age of the subject, also is of a certain importance As soon as the injection passes into the cavity, it increases to a size greater than before the pus was evacuated Percussion shows this to be due to the sudden vaporization of the ether The sonority persists for several days, sometimes a week, and gradually, as the ether vapor disappears, becomes dull No matter what the amount of ether injected, he has at no time noticed any sign of excitation, of anæsthesia or of narcotism The long sojourn of the iodoform in the purulent sac is well determined In one case he found appreciable traces at the end of five months From two to four injections are generally sufficient After the first operation the patient, in a few days, can be allowed to go about his ordinary occupations For small cavities, of the size, for example, of a large orange, a strong solution may be used of 20 grammes of ether containing 4 grammes of iodoform, which will produce energetic action and prompt relief, the larger cavities require a weaker solution, the action is prolonged and relief slower

Dr Chantemesse, at the request of Prof Verneuil, has made some interesting experiments bearing upon this subject in the laboratory of Prof Cornil He took some of the pus which was drawn from a cold abscess by the first puncture, and with it inoculated two guinea pigs, they were killed two months later, and presented numerous tuberculous foci The emptied sac had been filled with the iodoform ether injection, and several weeks later a second puncture was made, the liquid in its turn being used to inoculate two new guinea pigs, they remained perfectly well and exempt from all tuberculous infection, as was demonstrated by the autopsy made some time afterwards

An Operation for Fistula in Ano —At the meeting of the New York Obstetrical Society, on January 6, Dr T A Emmet referred to the difficulty experienced at times from leakage after the usual operation of division of the sphincter for fistula in ano, and said that, to avoid this accident, he adopted another procedure recently The internal fistulous opening was about half or three quarters of an inch and a half to the left of the anus He placed the woman in Sim's posture, introduced a rectal speculum, and divided the tissue with the scissors as far up as possible without involving the sphincter Then Dr Bache Emmet, who was assisting him, put one finger into the rectum, bringing the rectal surface under the cut, and enabling him to denude the entire tract of the sinus without enlarging the opening into the gut While the parts were held in this position he inserted the first suture into the integument, close to the sphincter, outside, passing it through the lower edge of the internal opening of the fistula, and he so continued to pass interrupted sutures of catgut, approximating the mucous surfaces within the rectum more closely He thought the operation might have been more easily performed had he inserted sutures in the walls of the fistula outwardly before using the scissors, as it was, he experienced great difficulty in passing the sutures so deep The result had been perfect Such an operation would prove of great benefit if we could thereby cure the disease and avoid dividing the sphincter muscle —*N Y Med Journal*, June 27, 1885

Faradization in Intestinal Obstruction —M Laborde relates a case in which, the usual expedients having been tried in vain, one electrode of a Gaiffe apparatus was applied to the anus, and the other promenaded over the abdomen the current being varied in intensity, for fifteen minutes As this had no effect, the anal electrode was kept in place, and the other held steady on the hypogastrium After an energetic current had been passed for ten minutes, gurgling was heard, and flatus was passed, followed by about a spoonful of greenish liquid The application was then repeated, an enormous discharge of gas and fæces took place, and the patient was relieved at once —*N Y Med Journ* , June 27, 1885

SATURDAY, JULY 25, 1885.

ORGANIZATION OF THE INTERNATIONAL CONGRESS OF 1887. THE TWO RADICAL MISTAKES AND WHO MADE THEM.

It is always unpleasant to differ from those whom we have regarded with respect if not actual deference, and yet there are times when stern duty demands that simple facts should be stated in plain language, whether they prove palatable or unpalatable to friends or foes. The arrogance with which a few members of the profession in the cities of Philadelphia, Baltimore, Washington, and Boston, assume to constitute not only *the* profession of those cities, but also *the* representatives of all the respectability and science of the profession in the United States—the bitterness with which they assail the American Medical Association—and the odium they attempt to cast upon the representatives from each State, chosen by the Association to constitute a part of the Committee on organization of the Congress, through their chosen organs, the *Medical News* of Philadelphia, the *Medical Record*, of New York, and the *New York Medical Journal*, of the same city, make it necessary to analyze this seemingly heterogeneous mixture of arrogance, bitterness, and misrepresentation, to lay bare its true animus, that if any important mistakes have been made the medical world may see clearly what the mistakes were and *who made them*.

What then are the essential facts underlying all this tempest of words? At the Annual Meeting of the American Medical Association, in May, 1884, the President, Dr. Austin Flint, in his annual Address, called attention to the desirability of having the Triennial International Medical Congress hold its meeting for 1887 in this country, and after stating the fact that the Association was the only organized representative of the whole profession in the United States, distinctly recommended the appointment of a Committee to report upon the propriety of extending an invitation at the meeting of the Congress which was to assemble in a few months in Copenhagen.

This part of the President's Address was referred to a Special Committee, which at a subsequent part of the same meeting of the Association, reported a series of resolutions endorsing the recommendation of the President and providing for the appointment of a Committee of seven (which was subsequently made eight) to proceed to the meeting in Copenhagen and present the invitation in behalf of the profession of the United States, and if the invitation was accepted, the same Committee was authorized to continue its existence, add to its numbers and make all necessary arrangements for the meeting and organization of the Congress. Here are clearly presented three important facts, viz.: (*a*) that the American Medical Association is the only organized representative of all departments of the profession in the United States; (*b*) that the Committee of invitation with all its powers and duties was simply the instrument or agent appointed by the Association to perform certain acts or duties; and (*c*) having appointed such agent and invested it with certain important powers, the Asssociation was, by the fundamental principles of parliamentary law as well as by the dictates of common sense, itself responsible to the medical world, both for the character of the agent or Committee, and the manner in which it should discharge its duties. The truth of these statements is too obvious to require comment or illustration. The Committee was appointed, attended the Congress in Copenhagen, presented the invitation in accordance with the instructions of the Association, and it was accepted. Thus far all was right. Soon after the return of the members of the Committee of eight to this country they began their work of organization, and one of their first duties was to enlarge their number by selecting a suitable number of representative members of the profession to give their Committee, as enlarged, a more nationally representative character.

It was here, directly upon the threshold of the most important part of their work that a majority of the original Committee practically ignored all allegiance to the National Association, and assuming an entirely independent attitude, at once placed in the front of their ranks not only one who was well known to have repudiated the National Code of Ethics and to occupy a position directly hostile to the National Association and the State Associations throughout the country, but urged the addition of another still more obnoxious, until their Chairman, Dr Austin Flint, whose well earned reputation had contributed more to give character to the Committee than that of any other two members, felt compelled to tender his resignation as a member of the Committee, and was only induced to recall it, by an agreement that the objectionable additions should not be further urged Having enlarged their Committee by the addition of fifteen or twenty prominent members of the profession, chiefly from the three cities of Philadelphia, New York, and Washington, with two from Boston, two from Chicago, one from Cincinnati, one from St Louis, and perhaps one or two from other cities, the next step was a meeting of the Committee, as enlarged, in the City of Washington, November 29, 1884, at which there were present fifteen of the twenty-five members then constituting the Committee The deliberations were confined to a single day A Sub-Committee of three members of the original eight had prepared a series of rules, by which a large number of Sections were provided, the working of each and of the general sessions of the Congress, were to be regulated, and by which the Committee itself was to be officered and governed Under the guidance of a temporary Chairman and Secretary the report of this Sub Committee was taken under consideration, and so far as related to the simple rules regulating the practical working of the Congress, they were adopted with unanimity

But the rule providing for the American membership of the Congress proposed no representatives or delegates from either national or State medical organizations, they were to consist simply of such members of the profession as the Committee on Organization might graciously invite And it was not until after a pretty free discussion that a substitute offered by one of the members of the Committee, from Chicago, was adopted, making the American membership of the Congress consist of delegates regularly elected by the American Medical Association, the several State and local societies, and the several national organizations of specialists This, however, was the only important point gained in the direction of nationalizing, in opposition to centralizing, the work of the Committee, although a few members present continued to exert all their influence in that direction throughout the session, and subsequently by correspondence with the executive part of the General Committee The rule adopted regarding permanent officers of the *Committee provided* that all the general officers of the Committee should also be nominated (and of course elected) for the same official positions in the preliminary organization of the Congress, and that the executive Committee of the Committee on Organization should also be the Executive Committee of the Congress Under these rules, when the permanent officers of the Committee had been elected, and the chairmen of the several Sections named, it was found that eight of the twenty-five members of the Committee had been placed in position for general officers of the Congress, four more for members of the Executive Committee, and still four others for chairmen of Sections, making sixteen of their own number appointed to as many of the chief official positions in the Congress If a parallel to this can be found in the proceedings of any previous committee on the organization of a Medical Congress, we would like to know when it occurred and to what nation the committee belonged A few members of the Committee earnestly protested against this wholesale self-appointment to office, and urged a wider distribution of the more important selections But the uniform answer was that no one must be selected who was not well known both in Europe and America, and unfortunately, in their estimation, no one in the whole profession of the United States possessed these essential qualifications but themselves and a score or two of their personal friends in a few of the chief cities

When the General Committee adjourned its meeting in Washington, the filling up of the details and the selections for minor positions in the Councils of the Sections was committed to an Executive Committee with power to call another meeting of the General Committee to revise and complete its work at such time as it might deem proper, the general wish being expressed that another meeting might not be found necessary until the time for the National Association to meet in New Orleans, in the *following* May It is sufficient to say that the Executive Committee prosecuted its work in the same spirit and under the same narrow impulses that had characterized the beginning of the Committee work, and just a few weeks before the meeting of the Association in New Orleans it assumed the responsibility of publishing the results, not only in contempt of the Association, but without calling a second meeting of the General Committee, and thereby cutting off all opportunity to have their work reviewed even by those who had been added to the Original Committee, and thereby made in a measure jointly responsible for the results

We have given the foregoing detail of facts regarding the doings of the Committee on the Organization of the Congress as originally constituted, at the risk of being tedious, that all candid men, both in this country and in Europe, might see who was responsible for "injecting the Code controversy into the organization," by wantonly and unnecessarily thrusting men who had repudiated the Code, and openly condemned the National Organization, into the front rank of official positions at the very beginning of the work of organization. If the logic of events ever proved anything in human history, the events we have briefly detailed, taken in connection with the pompous attitude at present assumed by a handful of otherwise respectable members of the profession, in the cities of Philadelphia, Washington, Baltimore, and Boston, prove two things with the utmost clearness. The first is, that the majority of the Committee on Organization as at first constituted, whether consciously to themselves or not, practically made a bold attempt to use the national character and prestige of the American Medical Association as a "decoy duck" to obtain, first, their own appointment as a committee, and second, from the International Medical Congress in Copenhagen an acceptance of the invitation to hold its next meeting in this country, and having accomplished these, to coolly turn the Association into a "foot-ball" and contemptuously kick it out of their way, that they might organize the American part of the proposed Congress in the interests of themselves and a score or two of personal friends in three or four cities, entirely regardless of the interests or wishes of the general profession of the United States, in whose name the invitation had been given. Unfortunately for the final success of their scheme, the "foot ball" proved too heavy, and their kicks only resulted in breaking their own toes.

Smarting under the injury done to their pedal extremities, they first vociferously denounce the Association and all connected with it. And yet, no sooner had the Association added a sufficient number of new men to the original part of the Committee to dress their wounds, drop out the specially obnoxious ones, and make their places available for a wider distribution of the official positions, and kindly offer to continue all the rest as before, then they, by concerted action in three or four cities, throw themselves back on their supposed dignity, and in the exact spirit of the modern labor union strikers, refuse to accept any positions themselves or let any one else, if they can prevent them, until the American Medical Association shall with all due humility take itself and the new members out of their way, and allow them to join their old *Code*-repudiating comrades and again fix all things up in their own way. Such is the exact position of a handful of very respectable members of our profession in four cities, who committed the two radical mistakes of supposing they could use the American Medical Association alternately as a *decoy duck* or *foot ball* at their pleasure; and that in themselves and a few friends were concentrated all the science and representative capacity of the medical profession of the United States. In view of their present position they might with great propriety adopt the prayer of Scotland's favorite bard,

"O wad some power the giftie gie us
To see oursel's as others see us!
It wad frae monie a blunder free us,
And foolish notion."

That we do not err in representing them as a handful or limited number, is proved by the letter of our special correspondent in Philadelphia, on a subsequent page of this number of the JOURNAL. The writer of that letter is one of the most eminent and widely known teachers in the profession of Philadelphia, and his letter will be read with much interest.

Meanwhile, the real friends of the International Medical Congress may rest assured that the American Medical Association, through its present able and judicious Committee of Arrangements, will fulfill all the obligations it incurred, in extending the invitation at Copenhagen, in the most liberal and enlightened manner.

CHOLERA INOCULATION.

The idea that a disease, one attack of which is well known not to destroy susceptibility to future attacks, can be prevented by inoculation with any possible preparation of its efficient or specific cause, is so contrary to the simplest rules of induction, or, in other words, to "common sense," that one feels a degree of surprise that any intelligent medical man should waste his time in experimenting on the subject. But it appears that nothing is so extravagant or absurd, especially if connected with the modern germ theories of disease, but that it may find advocates willing to experiment wherever they can find deluded subjects willing to be used for that purpose. That one attack of genuine epidemic cholera does not afford the individual immunity from subsequent attacks of the same disease is well known to all who have had practical experience with the disease. A correspondent of the *British Medical Journal*, of June 27, writing from Valencia, in Spain, says: "I know people at home and abroad, and have patients here, who have had it twice and thrice and some have died of it after one attack." Yet the same writer tells us that a Dr. Ferran claims to have taken the genuine Koch bacilli from the intestines of a patient who died of cholera in Marseilles last year, and by cultivation has discovered the "basic cell of the comma-bacillus"

These basic cells he has called "peronospora Ferrani," and it is by inoculation with these that he claims to protect the people against a liability to be attacked with the cholera The same correspondent states that in the city of Alcira alone, some 6,000 or 7 000 persons were inoculated and re-inoculated by Dr Ferran and his assistants, who claim that it produces no severe or dangerous symptoms, and secures to the re inoculated entire immunity from attacks of cholera But the correspondent tells us that cases of "phlegmonous erysipelas, septicæmia, and death," following the re inoculations, have already come under his own observation And so far as prevention of cholera attacks is concerned, subsequent observations have shown that wherever the disease has prevailed, it has attacked the inoculated as readily and fatally as the uninoculated It is stated in the secular papers of July 18, that "every one of forty seven nuns who were inoculated by Dr Ferran has since died of cholera" It has been stated several times that the Spanish government had forbidden the further operations of Dr Ferran in that country but it appears that he still finds deluded victims willing to submit to his futile and somewhat dangerous experiments

DISEASE FROM POISONOUS DRIED BEEF

A number of cases of an affection resembling, according to newspaper accounts, a severe form of cholera morbus, occurred in Momence, Illinois, on July 17, which was evidently due to the eating of decomposed dried beef The whole number of persons affected was about forty There scarcely seems a doubt that poisonous dried beef was the cause of the sickness, as it has been shown that every person affected had partaken of the beef, and so far as can be ascertained no one was taken sick who had not eaten of it

The dried beef was shipped to Momence from one house in Chicago, but the dealer declares that the meat was good when shipped by him In view of the fact that the beef was shipped on Tuesday and put on sale at Momence on Wednesday, the disease appearing on the following Friday, it scarcely seems possible that the statement of the shipper can be correct The dried beef, ninety-seven pounds, was shipped in a box, and after its arrival was unpacked and done up in paper until sold There are statements to the effect that when received at Momence the beef appeared to be fresh and sweet smelling, and the retailer states that he noticed no bad odor from it

The symptoms of those affected, according to newspaper accounts, were great languor and weakness, nausea, gripings, severe diarrhœa and vomiting It seems also that typhoid symptoms developed in a few cases, though there has only been one death Dr Utley, of the State Board of Health, saw a number of the cases in consultation with Dr Keyser, of Momence, and Dr Ellis, of Kankakee Dr Utley's opinion, according to the *Chicago Times*, of June 15, is that the poisoning was surely caused by the beef, and after careful examination it seems impossible that the person putting up the meat did not know it was poisonous As no autopsy of the person who died was allowed, the examination was necessarily incomplete It is stated that Dr Keyser, on microscopical examination with 600 diameters, found numerous "animalculæ"

Dr O N Ellis, of Kankakee, says From partial examination under the microscope of the impure beef, I find the marked characteristic to be a very unpleasant odor, made more apparent by being macerated for a short time in pure water at ordinary temperature I find a total breaking down of striated muscular fibres, the presence of which in healthy muscle would be the first distinguishing characteristic when examined microscopically This destruction of muscular tissue also means the entire oblitaration of the myolemma or fibrous covering of the muscle with blood corpuscles and fatty tissues, which leads me to believe that this beef was taken from an animal diseased, or, more probably, one partially decomposed, before submitted to the so called process of curing, presenting a substance that is regarded as poisonous in the extreme when eaten, and hence dangerous to human life

So far as can be ascertained, the most complete examination of the meat yet made is that of Professor G A Mariner, of Chicago His microscopic examination has disclosed the presence of numerous bacteria, including micrococci, bacilli (including bacillus subtilis and bacillus anthracis), bacterium termo, vibrio serpens, spirochætecæ obermeieri, and spirillum volutans Examination of the muscular tissue showed that it was infiltrated with micrococci and partially or wholly broken down There was no odor in the specimens examined by Prof Mariner

Health Officer De Wolf, of Chicago, is inclined to attribute the sickness to the development of ptomaines in the beef, and from the meagre account which we have been able to obtain we are inclined to agree with him In fact, we see no reason for holding to any other theory But aside from this, it must be concluded that the whole affair is the outcome of criminal negligence on the part of some person or persons, and they should be punished to the extent of the law

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, July 6, 1885

1ST VICE-PRESIDENT, C W PURDY, M D,
-IN THE CHAIR

DR ROBERT TILLEY exhibited to the Society

MICROSCOPICAL SPECIMENS OF THE FUNGUS, ASPERGILLUS GLAUCUS TAKEN FROM THE HUMAN EAR, AN OSTEOMA DEVELOPED FROM THE CRUSTA PETROSA OF A CANINE TOOTH, AND FILAMENTS, OR MYCELIA, FROM THE BODY OF A TONSIL

Dr TILLEY said In describing to you the three specimens which are exhibited under the microscrope, I will refer in the first place to the fungus—aspergillus glaucus—taken from the human ear I have had this in my possession for about three years and have shown it to several of my acquaintances, but did not deem it of sufficient interest to exhibit it before It is, however, an object which many have not seen before, although it is mentioned in every text book on the subject I have no intention whatever of entering into the question of the aspergilli in general relative to their influence when found in the ear But I must say that my experience relative to the question leads me to think that its influence as a source of pain in the external ear is greatly exaggerated in the books This specimen was taken from the posterior wall of the meatus of a little girl who had for some time previously been afflicted with otorrhœa The otorrhœa had however ceased and the fungi were recognized in lusty growth immediately on looking into the ear There was, however, no pain complained of, the patient was brought rather for inspection than for the expectation of relief You will observe that the fungi are growing on what by simple inspection might be called dried but otherwise normal wax You will notice that the fungus consists of one straight long stem surmounted by a round ball, very much like the top of an onion which has run to seed It is commonly said, I think rather on theory than on observation, that they are caused by sleeping in low, damp apartments The child from whom this was taken belonged to people in good circumstances and was well taken care of, and was not living in damp quarters

The next specimen, to which I now refer, is the osteoma developed from the cementum or crusta petrosa of a canine tooth I am very sorry that I cannot give you anything of the clinical history, because I believe it would be interesting if known In consequence of this, it is perhaps necessary that I should give a word of explanation as to how it came into my hands A friend was speaking to me of some one who had been subjected to the operation of drilling through the fangs of six teeth on account of what was called "ossification of the nerve" In speaking to one of my acquaintances among the dentists about such a condition, I was presented with a tooth a section of which I exhibit to you You will see, both macroscopically and microscopically, that the line of demarcation is well defined You will further see that the general appearance of the tumor is that of bone, and that it differs greatly from the general appearance of the tooth proper It is interesting to observe, moreover, that the canal, through which the nerve and vessels enter, is greatly diminished in its course through the tumor, consequently great pressure must have been exerted on the nerve Before making the section, I had supposed that the canal was completely obliterated, so small is its opening at the end of the tumor On looking at the specimen through the microscope, you will see very clearly that while the line of demarcation between the dentine and the proliferation of the crusta petrosa is well marked, and the lacunæ and canaliculi of the bony structure of the tumor well demonstrated, there is also a number of contorted tubules in the bony tumor which resemble, somewhat, the dental tubules Haversian canals are of course not present, they never are in such growths

Although I have no clinical history to present, I may add that the usual clinical history is one of severe pain, which nothing but extraction seems capable of relieving The last specimen is one which I obtained from one of those little pockets which are often found in the tonsils They seem to come and go, sometimes without giving any more inconvenience than a little discomfort They are frequently associated with fœtid breath, and in some cases the masses themselves are very offensive (in odor) In the present case, however, this was not so, there was no fœtor There was, however, an unpleasant sensation amounting to a positive discomfort running down the neck externally, in the direction of the sterno cleido mastoid (muscle) On pressure around the mass, the little mass popped out, suddenly, so that it came near going down the patient's throat In examining it, under the microscope, it proved to be one base of filaments, very fine and containing spores in the body of the filaments, and associated with them fat crystals I succeeded in staining them with methyl violet, but only after first extracting the fat with ether

I have no theory to present, gentlemen, I simply exhibit to you what has been interesting to me After the removal of the small mass I did not think any treatment was necessary, but as there was a little bridge of tissue more or less dividing the cavity into two sections I divided the bridge with the electro-cautery

DR J A ROPISON read a paper on

THE TREATMENT OF ACUTE CORYZA

He said the literature on the subject of the treatment of acute coryza is scanty and of a stereotyped nature The profession seems to have arrived at two conclusions, first, that it is not a disease of sufficient severity and importance to command special attention, second, that no plan of abortive or curative treatment has been sufficiently successful to cause them to investigate the subject farther However, in view of the fact that repeated attacks of acute coryza undoubtedly have a causal relation to pathological changes in the nares which it is difficult to remove, and that we are so frequently consulted by public speakers and singers who beseech us to abort or rapidly cure such acute attacks, it certainly deserves more than a passing notice.

The time honored plan of aborting an attack of acute coryza by the administration of a full dose of opium, an active purge and a potent diaphoretic, has proved more disagreeable than efficacious. The plan, advocated by Dr. Ferrier, of blowing into the anterior nares a powder composed of morphia, bismuth and acacia, has been quite satisfactory in a few instances, but it is not free from the objection that, when successful, it often produces an unpleasant nausea. Its success is undoubtedly due to the sedative and astringent effect upon the inflamed mucous membrane.

What are the pathological conditions in the first stage of acute coryza? Briefly, there is dilatation of the capillary vessels, the arterioles being dilated and the venules engorged, inducing tumefaction of the mucous membrane. This is accompanied by dryness and pain. Secretion is abolished. In reflecting upon these circumstances the thought naturally arises, whether, if we can employ such measures or drugs as will antagonize these abnormal states, we will succeed in aborting disease. We have recently had added to our armamentarium a drug which more completely antagonizes in its physiological actions these pathological conditions than any other. It is the hydrochlorate of cocaine.

Its physiological actions have been demonstrated to be concisely as follows: when applied to a mucous membrane it is a potent although transient anæsthetic, a vaso motor constrictor causing contraction of the arterioles and depletion of the venules, thus rapidly emptying congested tissues of a surplus of blood. This drug is also an astringent and has the property of lessening the secretion of muciparous glands. On studying the relation between the state of the nasal mucous membrane in the first stage of acute inflammation and after an application of cocaine, the theory was formulated that cocaine should prove useful in aborting acute coryza, and it was determined to try it on the first opportunity.

The details of the first experiment are as follows: Miss S———, a soprano singer in one of our city churches, applied to me on the morning of February 22, and desired immediate relief from a "cold in the head." She complained that the previous night she had been exposed to a draft and awoke that morning with the cold, as evidenced by the fact that she could not breathe through the nose, and that her nose felt dry and painful, and she had lost the sense of smell. Inasmuch as she had to sing that night at a special service, she must have immediate relief. Upon examination I found all the conditions incident to the incipiency of an acute coryza. Her temperature was 102° F., with some acceleration of the pulse.

Febrifuges and a mild diaphoretic were prescribed. A local application of a four per cent solution of hydrochlorate of cocaine was applied, as thoroughly as possible, to the congested mucous membrane, and the parts were sprayed, also, for some time with a warm alkaline spray, hoping thereby to reduce the hyperæmia. After having made another application of the cocaine, the patient was instructed to return home and follow the same line of treatment and to return the following day. She did not return until three days later, when she reported, to my surprise and gratification, that she had been able to sing as desired, and that no symptoms of the disease had returned.

The success which attended this new departure, induced me to try it in other cases of acute coryza which were seen early, and it has almost always been successful. Of course, the number of cases which we see in their forming stage are few, on account of the fact that the patients do not seek medical advice for this affection until the disease is well advanced.

In the use of cocaine for the purpose of aborting an acute coryza there are some objections, it has to be applied often in order to maintain its action on the inflamed mucous membrane, and it is an expensive drug. I have found that the use of a warm alkaline spray serves to prolong the sedative action of the cocaine. Of course dependence is not to be placed on local measures alone, but in addition proper attention is to be given to constitutional and hygenic treatment.

Dr. Tilley said he had used the hydrochlorate of cocaine in two or three cases of acute coryza with much satisfaction. According to one patient an attack had ended with a single application. While he did not look upon cocaine as a sure cure for acute coryza, he thought it almost always did good. He referred to a serious accident which occurred to one of his patients during the use of cocaine. The patient was a boy aged twelve years, in whose nose a little cocaine had been used. After the first application he suffered a little nausea, which was not regarded as serious, after the second application the nausea was worse, but it was not until a third application had been made that the symptoms became alarming. These symptoms were difficulty of breathing, syncope, irregular action of the heart, cold perspiration and loss of sensation in the extremities. Notwithstanding these symptoms were alarming, the boy recovered quite rapidly. He had noticed reports of cases in the journals where the same symptoms had appeared.

Dr. Weiler said that he had had a good deal of experience in the use of coca, especially in the form of the fluid extract. He had taken large doses, in his own person he had used two pounds in a short time. Formerly he had considered it as harmless as tea, but latterly he had arrived at the conclusion that it is a powerful narcotic. The strange phenomena which follow use of cocaine in some cases, he believes to be due to the narcotic action of the drug, and that they would not appear if the drug was not given in large doses. He believed some patients to be peculiarly susceptible to the action of coca or cocaine, similar to the idiosyncrasies of patients in the use of belladonna, opium, and alcohol. In the case mentioned, he believed the symptoms to have been the result of an over dose of cocaine. In his experience, he had found a two per cent solution of cocaine strong enough, and urged the tentative use of the drug in the same manner as in the use of morphia

Dr Webster did not wish to be considered sceptical, but he had some doubt as to the alarming symptoms in the case mentioned having been due to the drug Is it not possible they were the result of reflex processes in over-sensitive patients? He had a patient recently who vomited after holding a fever thermometer under her tongue

Dr Paoli believed that the old treatment of acute coryza by giving the patient a hot bath, muriate of ammonia internally, and inhalations of camphor in hot water, or the oil of eucalpytus, combined with borax, to be the best, although he would acknowledge that cocaine would often relieve severe attacks in a short time

Dr S J Jones asked the author of the paper if he had used cocaine with a steam atomizer in recent pharyngitis, tonsilitis and laryngitis, also, if the applications of cocaine to different patients were from the same solutions and at brief intervals, so as to be able to state how a reliable solution acted on different patients

Dr Robison, in closing the discussion, said he did not advocate the plan of treatment as infallible or free from objections, nor did he neglect to use other means of cure if he thought they were advisable As to the effect of cocaine on certain patients, he had a similar experience to Dr Tilley in the case of a woman who had twice been operated on without cocaine for nasal polyps No unfavorable symptoms occurred during these operations At the third and fourth operations, cocaine was used and the patient was troubled with nausea, vomiting, palpitation of the heart and syncope As no cocaine had been used in the first two operations, these symptoms in the third and fourth operations seemed to be, undoubtedly, due to an idiosyncrasy of the patient He had not used cocaine with the steam atomizer, but he thought it feasible, if the drug were not so expensive He prepares fresh solutions for each patient so as to preclude all possibility of failure of action by reason of deterioration of the solution by age He had found the same package of cocaine to vary in its local and constitutional effect on different patients, affecting some more rapidly and profoundly than others

STATE MEDICINE

MICHIGAN STATE BOARD OF HEALTH

At the quarterly meeting of the State Board of Health of Michigan, held July 14, 1885, at its office in Lansing, the following members were present — Drs Avery, Lyster, Hazlewood, Vaughan, Tyler, and Baker

SECRETARY'S REPORT

The Secretary read a report of work during the quarter ending July 13, 1885, the leading features of which are as follows The weekly and monthly bulletins of Health in Michigan, and the meteorology and mortality reports had been prepared from the numerous reports received, and sent out as heretofore The footings and computations on meteorological registers and on the sickness reports and tables have been carried on, and the meteorological computations for the year 1884 nearly completed ready for tabulation The office had made large distributions of documents relative to the work of health officers, and to the restriction of contagious diseases, to newly appointed health officers and to others, especially in localities where such diseases have occurred

The proceedings of the Sanitary Convention at Lansing have been edited, sent to the printer, and the proof of most of it read Articles on meteorology and sickness in Michigan in 1883 have been completed from data previously collected Data collected by the office relative to scarlet fever in Michigan in 1884 have been compiled, and also that relative to diphtheria A map has been prepared showing the distribution of diphtheria in Michigan in 1884 Smallpox has been present in Michigan during the quarter, at Bellevue, Eaton county, Alba, Antrim county, Battle Creek, Girard township, Branch county, and South Haven The outbreak at South Haven was confined to those first exposed, and has been stamped out, after nine cases occurred, with one death The infection at South Haven was from a German emigrant who sailed from Bremen, April 12, on the ship Donau, North German Lloyd line The emigrant was broken out with smallpox when he reached South Haven, April 27, and might have been quarantined *en route*, and the outbreak thus confined to one case All infected persons were at once vaccinated by the health officer, but the virus was not good, and thus precious time was lost This outbreak is but another added to the many constantly recurring outbreaks of communicable disease in Michigan and the Northwest, to which a faithfully executed emigrant inspection service, carried on by the National Government, would put an end, or greatly lessen At the present time, so far as known, there is not a case of smallpox in Michigan Typhus fever was reported at Grand Rapids, Mich , during the week ending July 4

Cholera is spreading with great violence in Mediterranean Spain, hundreds dying daily It was reported present in Marseilles over a month ago, and July 10, at Toulon A strange and fatal disease, believed to be cholera, was also reported from Portugal Asiatic cholera will probable reach this country this year or next year, and the State Board of Health has prepared to meet the emergency by many lines of work, as best it could About 12,000 copies of the document on the best

METHOD FOR THE PREVENTION AND RESTRICTION OF CHOLERA

were distributed to the people last year The recent distribution of documents relative to typhoid fever, and especially the correspondence with health officers throughout many parts of the State on the best method of restricting this disease has done something in the way of drill in the two important methods applicable in case of cholera,—the disinfection of all bowel discharges and the protection of the purity of the water supply. Much, however, remains to be done in many localities in the way of abating nuisances, and in protecting wells from sources of contamination.

The Legislature has passed an act granting the State Board of Health power to establish a system of

INSPECTION OF EMIGRANTS AND TRAVELERS,

and the disinfection of baggage, etc., liable to be infected with cholera or other dangerous communicable disease, but the act was not given immediate effect and so does not take effect until September 18, 1885. The contingent appropriation to enable the Board to carry on the inspection, etc., provided for in the act, can be used on or after Sept. 18, in case the Governor thinks its use is necessary.

Reports relative to examinations during this quarter, by this Board, of plans for buildings, have been sent to the Boards governing the Michigan Asylum for the Insane, at Kalamazoo, the Northern Asylum for the Insane, at Traverse City, and the State Reform School, at Lansing. Over 650 pages of the letter-book have been used in copying the most important parts of the correspondence, and other branches of the office work have been large during the quarter, and the Legislature made additional demands upon the time of the office.

A very successful Sanitary Convention was held during the quarter at Ypsilanti.

The Board spent much time in examining plans, as required by law, of a proposed new

DOUBLE COTTAGE AT THE REFORM SCHOOL AT LANSING,

a building designed to accommodate 100 pupils. The plans were submitted by the architect, Mr. William Appleyard, of Lansing. The Board approved the plans for ventilating and warming the second and third floors. With reference to the first floor the Board recommended, in order to avoid the settling of dust in the registers, that iron hoods be placed over the fresh-air inlets which enter the school rooms through the floor, and that two additional foul-air outlets, each of a size equal to that of the present outlet, be provided for the two school-rooms, one in the west wall of the west room, and the other in the east wall of the east room, and that these shafts be heated by steam pipes. Each of these two school rooms is 30x40 feet, 18 feet high, designed to accommodate 50 pupils. Fresh air is brought into each room by two shafts having an area of 512 square inches. The foul-air shaft for each room is only one-half the size of the inlet pipes, the area being 256 square inches. The recommendation by the Board of Health is that the outlets equal the inlets in area. The method of heating and of taking fresh air into the building was approved, and also of the making of the basement floor of cement troweled smooth.

The SECRETARY presented a printed statement in regard to the charges made by a minority of the

LEGISLATIVE COMMITTEE ON INVESTIGATION,

and asked that a committee be appointed to fully investigate the conduct of the office, and the several laws governing the action of this Board. Drs. Hazlewood, Vaughan, and Tyler, were made such a committee.

The SECRETARY read a *resume* of the work of other State Boards of Health and of city boards of health, also a report in regard to recent legislation in Michigan in regard to

SUBJECTS RELATING TO PUPLIC HEALTH.

The act passed by the Legislature appropriating $10,000 as an epidemic contingent fund was read by the Secretary, and the Board appointed Drs. Baker and Lyster a committee to frame rules under that law and submit them to the committee, so that they can be in readiness in case of threatened occurrence of cholera, smallpox, etc.

The Board authorized the Secretary, should cholera appear in Michigan, immediately to proceed to the place, or send a competent person to confer with and aid the local board in

RESTRICTING THE SPREAD OF CHOLERA,

and it was informally agreed that if cholera appeared in the United States, the President of the Board should at once call a meeting. The revision of the document on restriction of cholera issued by the Board in 1884, and the printing of 20,000 copies for distribution, were ordered.

The Board directed that the names and addresses of Health Officers in Michigan be printed in pamphlet form.

The subject of

TYPHOID FEVER

was discussed, and the Secretary was instructed to issue a circular designed to collect information from health officers in localities where typhoid fever occurs, and a committee was appointed to prepare and have printed a document giving methods of preventing and restricting typhoid fever, the document to be distributed in localities where it occurs.

The Board considered the subject of the

CARRYING OF INFECTED ARTICLES AND BODIES DEAD OF CONTAGIOUS DISEASES,

and circulars relating to that subject were ordered printed and sent to health officers and to railroad companies.

The proceedings of the Ypsilanti Sanitary Convention were ordered printed in pamphlet form. Invitations from three places in Michigan to hold sanitary conventions were considered.

DOMESTIC CORRESPONDENCE

THE PROFESSION IN PHILADELPHIA AND THE INTERNATIONAL CONGRESS

Dear Sir.—The JOURNAL of July 11 contains a letter from your Philadelphia correspondent, in which he states that "there is no dissent to the determination in this city, that what has taken place at New Orleans and at Chicago, to the damage of the Congress, shall not be sanctioned even in appearance, or permitted to stand, as the work of Philadelphia at all, notwithstanding the fact, that a Philadelphian is charged with having had a great deal to do with it "

Your correspondent is very much mistaken There is dissent, and very great dissent, with the action of the twenty-eight or twenty-nine medical gentlemen A prominent medical man told me to day that he had refused to sign the resolutions of the twenty-nine I did not sign them I know many medical gentlemen in this city who, with myself, are fully in accord with the action of the American Medical Association at New Orleans We are also earnest in our desire to aid the committee appointed at New Orleans, and to help in every way we can, the arrangements for the International Congress It is not generally thought here that the action at New Orleans has done damage to the Congress, but quite the contrary

One of the twenty nine had six positions given him by the Committee of eight *Hinc illæ lachrymæ!* The Philadelphian referred to is presumably the Secretary of the Committee, appointed at Chicago, Dr J V Shoemaker His manly action at New Orleans has been greatly appreciated here, and he has many warm and true friends Twenty-eight or twenty-nine gentlemen do not represent the whole profession of this city I feel assured that the profession of Philadelphia will support the International Congress and the Code of Ethics of the American Medical Association I am very truly yours, etc P

Philadelphia, July 18, 1885 W H Pancoast

NEW YORK LETTER

(FROM OUR OWN CORRESPONDENT)

A Classical Expression of New York Heat—Tenement House Inspection—The New Hospital for Contagious Diseases—Lectures on Gastronomic Science—The New Liquor Analyst of the State Board of Health—Dr Edson's Report of his Sanitary Division—The Autopsy on Commander Gorringe—A Pathological Laboratory at the New York Polyclinic—Chagres Fever—Buddensiek's Sentence—Mrs Yseult Dudley at a Homœopathic Asylum

The time of midsummer dullness has come, when, as Horace astronomically expresses it,

> Procyon furit,
> Et stella vesani Leonis,
> Sole dies referente siccos

Consequently, everybody who could possibly get away, has gone to Europe, or has sought in the breezy mountains or beside the salt sea a retreat which

> flagrantis atrox hora Caniculæ
> Nescit tangere,

while those left behind in the heats and miseries of the town would fain cry out,

> O, rus, quando ego aspiciam ? quandoq licebit
> Ducere sollicitæ jucunda oblivia vitæ ?

The reports of the extra corps of physicians to make house-to-house visits in the tenement districts during the summer, which were handed in to the Board of Health, July 14th, show that during the first week of their work they visited 2,339 tenement houses, occupied by 10,081 families, and prescribed for 236 persons, chiefly children suffering from diarrhœal troubles These inspectors all agree that the sanitary condition of this class of dwellings at present is greatly superior to that which they found last year

On North Brother Island in the Sound, there is now approaching completion the new hospital for contagious diseases which is to take the place of the buildings now occupied for that purpose on the extreme southerly point of Blackwell's Island, East River A few days ago a party of city officials paid a visit to the new quarters on board the Health Department yacht " Franklin Edson," which is to be a part of the hospital system of the island and has been especially prepared for the transportation of the sick, with separate compartments for smallpox patients and those suffering from other forms of contagious disease The main hospital building is of brick, two stories high, heated and ventilated with most improved modern appliances There is a large ward on each floor, lighted on three sides, and overlooking each ward is a small glass-incaved room to be occupied by the nurses on duty when their actual attendance is not required at the bedsides of the patients This hospital is designed to accommodate seventy-five patients The plans call for ten additional frame buildings, capable of receiving forty patients each, to be used in case of an epidemic, but only three of these will be completed at present Situated at a convenient distance from the main hospital, and also from the proposed sites of the smaller buildings, is the kitchen, which is a double building so arranged that the attendants, food and dishes of other fever patients may not come in contack with those of smallpox patients In addition, there is a handsome and comfortably fitted-up two story brick structure, to be known as the administration building, which is designed for the residence of the physicians, nurses and attendants employed about the hospital All the buildings are to be heated by steam generated in a separate building, which is supplied with Croton water from a thirty thousand gallon tank, and illuminating gas will also be manufactured on the island North Brother Island has an area of about fifteen acres, and on its southern point is situated what mariners know as the North Brother Light-house The island formerly belonged to West-Chester County, and on a part of it there is an old tumble-down frame building which the authorities of that county used as a smallpox hospital

Miss Parloa, one of the leading authorities on gastronomic science in this country, has been giving a course of five lectures on the subject, "How to cook for the sick", before the Training School for Nurses, at Charity Hospital, Blackwell's Island, an innovation in the instruction which might be adopted with advantage in other similar institutions

The State Board of Health has appointed Dr Englehardt official chemist and analyst for beers and distilled liquors The Board recently issued a circular addressed to all distillers or brewers of spirituous, fermented, or malt liquors in the State, notifying them that a law (a copy of which was appended), had been passed by the Legislature, which, in addition to duties covered by that of 1881, concerning which regulations of the Board had already been framed and published, specifically imposes upon the Board of making at least annually an examination of samples of all such liquors manufactured or offered for sale in any brewery or distillery in the State The circular goes on to state that while in no case will violations of the law be condoned or connived at, yet investigations will be conducted in a spirit of fairness and with proper regard for all vested business interests Also that information of the violation of any provisions of the statute will at all times be gladly received at the central office, where such use of it will be made as in the judgment of the Board will best carry out the intent of the law and best conserve the interests of the public

Dr Cyrus Edson has sent to the Metropolitan Health Board a report of the work done by his Sanitary division during the three months ending June 30, from which it appears that 15,890 pounds of beef, 64,596 pounds of pork, 14,170 pounds of poultry, 3,010 pounds of cheese, and 181,538 pounds of fish were seized as being unfit for human food The sale of 195 packages of adulterated tea was prohibited, while 1,622 specimens of milk were examined, and 194 quarts found to be adulterated During the quarter the inspections made by the force under Dr Edson were as follows At markets, 154, commission houses, 1,241, butchers' shops, 713, storehouses, 1,091, packing houses, 18, vessels, 126, stock yards, railroad depots, 209, and fish stands, 2,882

An autopsy was made in the case of Henry H Gorringe, the distinguished naval officer who transferred the obelisk so successfully from Egypt to Central Park, New York, and who died last week by Dr George L Peabody, in the presence of Drs Wm H Draper, H B Sands and E C Seguin, of New York, and Surgeon Thomas Hiland, of the Navy, Mr Gorringe's brother-in law It was found that death was due to sarcoma around the spinal cord and pressing upon it, the growth apparently having originated at the left side of the sixth dorsal vertebra There were also secondary deposits at the head of the sternum and in the lungs, liver and kidneys The disease had probably begun several months before the patient was confined to his room, and it was impossible to say whether the accident which he met with a year ago at Philadelphia in jumping from a train while in motion was concerned in its causation or not

A pathological laboratory has been fitted up in connection with the New York Polyclinic, and the Faculty has secured the services, as instructor, of Dr Frank S Billings, editor of the *Journal of Comparative Medicine and Surgery*

The steamship Colon, of the Pacific Mail Line, arrived July 15 from Aspinwall, and on reaching quarantine the captain reported that three men had died of Chagres fever during the voyage, and that two more were suffering from the same disease All those attacked with it were steerage passengers

Buddensiek, the notorious builder whose row of flimsy new tenement-houses tumbled down and killed one of the workmen engaged in their construction, has been convicted of manslaughter and sentenced to ten years' imprisonment at hard labor, together with a fine of $500 In pronouncing sentence the judge made some very sensible remarks, in the course of which he said that the jury in this case, the first of its kind in New York, rendered, in his judgment, a verdict in entire accordance with the evidence presented to them on both sides of the case The difficulty under which the defendant labored had arisen, he said out of a base motive to acquire money without giving any adequate return for it This man had built a very large number of houses in the city, and, so far as he had been able to learn, hardly one of them had been properly constructed It was simply an act of Providence that these buildings fell at the time when they did, before they were occupied, thus saving, no doubt, the lives of a great many persons In concluding he said "And I regret to say, from what I know of my own experience in this city, of a good many years' duration, that there are other people here engaged in the construction of the same kind of buildings as this man put up It is necessary to teach them that the consequences will be very serious to themselves, as well as to other people I have considered this case carefully, and have arrived at the conclusion that this man should be severely punished as a warning to other persons not to follow in his footsteps "

Mrs Dudley, the assailant of O'Donovan Rossa, who was acquitted on the ground of insanity, has been sent to the Homœopathic Insane Asylum at Middletown It was proposed to place her in the State Asylum at Auburn, but her lawyers succeeded in getting her consigned to the latter institution, as they believed that from it an earlier release could be secured P B P

NECROLOGY

DR JOHN CORSON

This able and well known physician died at his home in Middletown, Butler Co, Ohio, on June 19th, 1885 He had not been in vigorous health for some time, but was able to do professional work until very near the end His death, however was sudden and unexpected, being caused by basal meningeal hæmorrhage

Dr Corson was born in Butler Co, Ohio, on June 29th, 1825, and was married to Miss Caroline Martin in 1852 He graduated at the Medical College of Ohio in 1863 He practised medicine in Jacksonburg, Butler Co, for twelve years, the remaining years of his life being spent in active practise in Middletown

He was a member of the Ohio State Medical Society, and of the American Medical Association He was possessed of a strong intellect, an unusual amount of common sense As a physician he was honest, earnest, industrious, intelligent, skillful, as a citizen, enterprising, public spirited and upright, as a friend, generous and true, and as husband and father, faithful, indulgent and affectionate.

No man in his community was more honored, no physician more respected and beloved. His wife died only about two months before him. Three daughters survive to bear this great bereavement.

BOOK REVIEWS.

Bedside Urine-Testing, A Clinical Guide to the Observation of Urine in the Course of Work. By Geo. Oliver, M.D. London. Third Edition, pp. 260. London: H. K. Lewis. 1885. New York: J. H. Vail & Co.

The author devotes the first three chapters of his work to a somewhat minute consideration of the physical characters of normal urine, pointing out the clinical significance of the usual variations therefrom. He next considers the forms of proteids found in the urine, dealing more in detail with peptonusia, its cause, significance, and the most reliable methods of its detection. He suggests that peptones may appear in the urine through failure of their precipitation on the duodenum, as by their excess after a heavy meal, or through a deficiency or excess of bile, the latter being the normal precipitating agent.

The succeeding four chapters are devoted to qualitative and quantitative estimation of albumin in the urine by means of proper tests, which were first introduced by the author over two years ago. Brief hints are also given on the clinical significance of albuminuria. Of the test papers for albumin, the author now advises the use of but two, viz.: the 'mercuric' and 'ferrocyanic.'" He no longer advises the papers to be dropped into the urine directly, but into 60 m. of water, to which the urine is afterwards submitted gradually by means of the pipette in varying quantities from 4 to 30 drops, "varying with the re-agent selected and the range of albumin detecting power prefered." Besides the advantages from this method of procedure claimed by the author,—such as securing a definite range of albumin detecting power,—in the case of the 'ferrocyanic' paper, it obviates its only source of error, viz.: the occasional throwing out of urates which is prevented by the large dilution of the urine. In the case of the mercuric paper, where a precipitate is formed, the correcting agency of heat must be called in to eliminate possible errors. This, however, is unnecessary in the case of the 'ferrocyanic' paper.

In the next three chapters, the author deals with the qualitative and quantitative estimation of sugar in the urine, and the clinical significance of glycosuria. In addition to the indigo carmine test paper proposed in the last edition, the author now brings forward a copper test paper made from the tartrate of cuprammonium, which is claimed to be a reliable test for the presence of sugar in the urine, and permanent after long exposure to the atmosphere.

The last two chapters are devoted to the consideration of the bile derivatives found in the urine, under the heading of what the author terms "choluria." The bile pigments found in urine are easily revealed by several acid tests, and the author adds to these another, viz.: a citric acid paper with heat. The necessity, however, of a reliable test for the bile salts has long been felt, and the author proposes as such a paper charged with acidulated antiseptic solution of peptone. A solution from such charged paper develops a white precipitation at once in contract with bile salts. A quantitative method is worked out from a standard of opacity, similar to the authors method of quantitative albumin testing. Some interesting and very important hints are suggested by the author on the clinical significance of the bile derivatives in the urine—notably their possible agency in the production of uraemia. The author is among the few writers who use the word albumin (termination *in* instead of *en*) as applied to serum albumin, which we believe is strictly correct.

The little volume bears evidence of much painstaking original work on the part of its author, in a most practical and important field. The profession is certainly indebted to Dr. Oliver for rendering it possible to readily form a really comprehensive idea of the morbid conditions of urine at the bedside of the patient, by means of his ingeniously devised paper tests. The practical value of such ready knowledge, available at the same time that other organs are passing under clinical inspection, can not be over-estimated.

ASSOCIATION ITEMS.

MEMBERSHIP BY APPLICATION.

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association. Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership.

Application for membership, accompanied with Five Dollars, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly Journal of the Association will be forwarded for one year.

Richard J. Dunglison, M.D.,
Treasurer.
Lock Box 1274, Philadelphia, Pa.

MISCELLANEOUS.

Compensation of Medical Counsel.—The Supreme Court of Michigan, in the case of Thomas *vs.* Caulkett, decided June 17, 1885, rendered a decision of some interest to the profession. In that case it was held that a contract between a physician and a party injured by a railroad company that the physician should go with the injured party to the counsel and medical advisers of the company and explain the nature and extent of the injuries, and receive as compensation for so doing an amount graded by the amount awarded by the company, was illegal and void Had the physician explained to the advisers of the railroad company the nature of his contract and employment, the contract would have been legal Reported in 24 N W Reporter, 154

FERRAN A CHARLATAN —The *Chicago Tribune*, of July 22, contains a letter from Barcelona, written by a pupil of Koch, containing an account of a visit to Dr Ferran He says I introduced myself as a student of Dr Koch, and the Spaniard treated me to a sneer, a bow, and an abrupt "What can I do for you?"

"I would like to learn something as to your inoculations," I began, adding, "I am an American"

"I do not propose to acquaint you or any one else with my secret," the doctor interrupted "It is my property and is not to be revealed, though ultimately I may sell the right to use it in other countries than Spain"

"You would steal my secret!" he sneered, and Dr Pauli opened the door, to indicate that the interview was at an end I came away feeling snubbed, but more determined than ever that I should see the matter to its end In my opinion the man was not a legitimate worker, and I wanted to find out his method

Having borrowed a suit and an apron from a tailor, and having stained his face and arms brown, he again sought out Dr Ferran in order to be vaccinated, as he was bent upon finding out as much as possible

"It was not a very pleasant experience to court, but I could not get the substitute, and there was no alternative, so three or four hours after I had visited the doctor I was again in his presence, and the assistant had me by the arm He jabbed a sharp bistoury under my skin at a point just above my left elbow in a business-like manner Then he took a bit of a brownish unguental substance and inserted it under the integument, covering the wound up with a wafer of sticking-plaster, the whole proceeding reminding me of a rude way of vaccinating to protect from smallpox The operation completed, the fellow told me that an eruption would appear at the seat of the vaccination, and that violent catharsis ("induced cholera" he called it) would follow As an adjuvant to this, he gave me three little pills, bidding me take one after thirty six hours, and the others at the 72d and 108th hours respectively

"Though I hastened to get out of the crowded hospital and to my hotel, that I might there examine the wonderful culture-fluid that I carried in my arm, some twenty minutes necessarily elapsed, and later I had the "symptoms" As soon as my door was closed I tore off the plaster and extracted as much of the unguent as I could There may have been microbes in the stuff I hope so My analysis showed that it was a compound of something more than culture-fluid In it was elaterium, and croton oil, and vaseline, and perhaps other ingredients! In the three little pills were the same drugs—both of them the most violent of cathartics Subsequently I found that all who are vaccinated have to take the pills The result any physician or druggist can tell of

"It is charlatanry To disprove it is an impossibility Unless mine was an exceptional case, the inoculations consist in a subcutaneous *injection of* powerful hydragogue cathartics, under cover of a *bona fide* vaccination, supplementing this treatment with a dosing with pills of the same trash The croton oil under the skin causes an eruption and a sore that rapidly becomes pustular and painful The elaterium helps the oil to be efficacious, and it produces a systemic action which, in the depression that follows, simulates the choleraic collapse The dejections have an appearance and a composition similar to the "rice-water" discharges that are so characteristic of cholera In truth, the action of these two cathartics—especially if followed by dosage at intervals of thirty-six hours for nearly five days—will produce a condition strikingly analogous to the terrible epidemic It is a grand piece of fraud If any one doubts it, the Ferranian experiments can be had with the drugs, and a certainty of the symptoms that the Madrid Academy dilates upon so eloquently

"I wonder at such a stroke of smartness in a Spaniard, and humbly hope he is not an American in disguise The thing has the flavor of wooden nutmegs decidedly, and at any rate the man is a genius who can gull thousands and attract universal attention by taking the name of the cholera microbe in vain, and physicking people so deftly that they have the redeeming symptoms of a disease that will not be trifled with in any such way"

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JULY 12 1885 TO JULY 17 1885

Lieutenant Colonel E P Vollum, Surgeon, to be relieved from duty in Dept East on the expiration of his present leave of absence, and to report to commanding general Dept Platte for assignment to duty as attending surgeon at the headquarters of that department (S O 159, A G O, July 14, 1885)

Major J V D Middleton, Surgeon, leave of absence extended fifteen days (S O 159, A G O, July 14, 1885)

Major J M Brown, Surgeon, Captain Clarence Ewen, Assistant Surgeon, Captain A W Taylor, Assistant Surgeon, and First Lieutenant W C Borden, Assistant Surgeon, ordered to prepare for field service (S O 64, Dept Platte, July 9, 1885)

Captain W W Gray, Assistant Surgeon, relieved from duty at Ft Barrancas, Fla, and ordered for duty at Ft Columbus, New York Harbor (S O 147, Dept, East, July 13, 1885)

Captain Junius L Powell, Assistant Surgeon, ordered from Dept East to Dept of the Mo

First Lieutenant Henry P Birmingham, Assistant Surgeon, ordered from Dept Mo to Dept of the East (S O 155, A G O, July 9, 1885)

First Lieutenants G L Edie and C S Black, Assistant Surgeons, ordered for duty with troops en route to Dept Mo (S O 78, Dept Texas, July 15, 1885)

RESUME OF DR J MORTIMER GRANVILLE'S BOOK ON NERVE VIBRATION AND EXCITATION, WITH NOTES OF CLINICAL EXPERIENCE WITH THE PERCUTEUR[1]

BY ASA F PATTEE, M D ,
OF BOSTON MASS ,
PROF MATERIA MEDICA AND THERAPEUTICS COLLEGE OF PHYSICIANS AND SURGEONS AND LECTURER ON DISEASES OF THE NERVOUS SYSTEM

My object in reading this paper is to introduce more generally to the American medical profession the ideas of the somewhat eminent English physician and author, J Mortimer Granville, M D , on nerve diseases and their treatment, as set forth in his recently published book entitled "Nerve Vibration and Excitation " Dr Granville has for the past ten years or more been before the English medical profession as an investigator and author, and his contributions to the *London Lancet* have attracted the attention of scientific minds in this country, as well as in Europe, and looking upon this book as the accumulated evidence which can come only after years of study and experiment, it may well be regarded as a valuable epitome

The earnestness and enthusiasm which he evidently feels in his labor, must be his excuse for the minutiæ and repetition of detail, as well as for the proclivity which his theories frequently exhibit of asserting themselves as *facts* upon the slightest provocation In this paper I shall freely use the author's own words, as best illustrating what he would have us understand to be his meaning, but in the application, or treatment, I shall give only my own clinical experiments and their results

We must look upon Dr Granville as the originator of this idea of mechanical nerve vibration as a curative agent in nerve troubles, and there can be no doubt that his theories, if they should prove correct, will throw much light upon the mysteries of many of the nervous phenomena His argument, as taken from various parts of the book, and arranged systematically, is as follows "When nervous tissue acts, its essential elements, viz —cells and fibres—vibrate It follows that by throwing these elements into vibration by mechanical movement, we establish a condition favorable to the discharge of nervous force from the centres affected, and at the same time stimulate the nerve centre when discharged, to develop new force, to compensate for the loss of energy expended in exercise Cells vibrate as bodies suspended in the intercellular stroma of the gray matter, and fibres vibrate as delicately poised rods, or strung cords within the partile cylinders, formed by internal prolongations of the neurilemma, or sheath "

"When deposits take place in the progress of disease, in the interstices of a nervous cell bed, or between or upon the layers, or partition walls of a nerve sheath, or when the connective tissue forming the framework of a nervous structure proliferates, the vibrations of cell or fibre are mechanically prevented, and the discharge, or transmission of nervous force from a centre, or along a nerve, becomes physically impracticable Normal vibrations consist of movements of the constituent parts of a nerve within its sheath, and when these become inordinate, or disorderly, they are propagated to the sheath itself and then become painful "

"Under this last mentioned condition, the wave of vibration is likely to be propagated along the sheath of the nerve, and through it to the sheaths of other nerves with which the first in order of disturbance may be mechanically related, either by direct contact, or through intervening tissues "

"It is necessary at the outset to distinguish between vibration and excitation The former does not always—though it does generally—involve, or induce the latter, and the latter—that is, excitation of a nerve—may probably be affected by other means than by vibration, even when a vibratile body, or instrument is employed, to excite the nerve, although the nerve is undoubtedly thrown into a state of vibration as soon as it becomes excited " He explains this seeming paradox as follows "When the practical physiologist (the only interrogator of nature whose results are wholly worthy, and entirely trustworthy, I mean the vivisectionist)—draws his needle with a light hand across the sheath of a nerve, or presses the point of his instrument upon it steadily, he excites the nerve or centre, which means that he throws it into vibration "

He says, in corroboration of this "Every organ in the body, from the liver to the testicle, may, in the absence of utterly disabling organic disease, be made to perform its proper function by exciting the nerve which supplies it with energy, by mechanical vibration "

---

[1] Read in the Section on Practical Medicine Materia Medica and Therapeutics at the Thirty sixth Annual Meeting of the American Medical Association

Though this statement sounds somewhat extravagant and premature, when we consider that this conclusion has been arrived at through the experience of but one man, and that, too, in support of a theory of his own, yet he hastens to confirm it by the following statement 'In this way I have seen the liver unloaded, and what seemed to be inveterate torpidity of the bowels remedied in a few successive vibrations "

I think every one will concur with me in praying that so far as the inveterate torpidity of the intestines is concerned, this statement may hold good In connection with this, I will give here his "notion" of morbid activity "My notion of morbid activity is this I believe, as previously affirmed, that under normal conditions, when a nerve-cell or fibre becomes active,—the one in receiving impressions, or discharging force, the other in transmitting sensory impressions, or reflex or direct motor impulses,—the essential elements of the nervous tissue vibrate mechanically in their beds or cylinders When either the vibration of cell or nerve are unrhythmical in themselves or discordant with the vibrations of other cells or nerves, which they may either throw into disorder, or inhibit (and perhaps this is the true explanation of the inhibitory process), they propagate the commotion the disturbance has set up to their sheaths or envelops, and the activity becomes disorderly and painful " Now this is, of course, simple conjecture, and ere we endorse it as "the true explanation of the inhibitory process," it would be wise to treat it after the direction we sometimes see on the bottle of some unfortunately compounded prescription "To be well shaken before taking" At least for the present it certainly ought to be labelled "unknown" and put aside for future investigation, with several other ingenious ideas which vibrated the author's brain at that time

In the chapter devoted to the conditions in which this instrument may be advantageously used, he gives us his definition of that condition known as "pain" I will quote only sufficient to make plain his meaning, collecting them *en masse*, as they are somewhat disconnected "If I am right in my theory that pain occurs when the vibration of the essential elements of nervous tissue extends to the beds of cells, and the sheaths of nerve fibres, it is easy to understand how compression of a nerve,—either by force applied directly to its trunk, as when the ulnar nerve is squeezed as it passes behind the inner condyle of the humerus, or by distension of the surrounding tissue, from congestion of the vessels,—or by effusion,—causes pain, and why the pain is proportioned to the constriction, short of extreme pressure, which must, of course, altogether prevent vibration of the nerve affected As the nerve is compressed, its sheath is forced in upon the nerve elements, and necessarily becomes irritated by their disorderly vibrations " As foundation for the support of this theory, he argues as follows "Without such an explanation as this theory of pain affords, it has always seemed to me unaccountable that so little pressure,—a very little at the most,—as can be caused by the congestion of a swollen finger, should occasion so much agony as is experienced, for example, in whitlow, or that the throbbing of the arteries should be as acutely and painfully felt as we know to be the fact In this way, also, one branch of a nerve whose sheath is vibrating painfully may communicate its vibrations to another sheath which happens to be in juxtaposition," etc , etc

I will make no further extracts from this part of the subject, but proceed to the *rationale* of this process of relief, which,—from what I have already quoted on nerve vibration and excitation, both natural and morbid—may easily be understood from the following "The *rationale* of the process of relief is to overpower the tumultuous vibrations of the nerve elements within their sheath, by communicating an independent and vibratile motion to the nerve as a whole " This will, I think, be sufficient as a key to the author's argument for nerve percussion

While he disbelieves that electricity possesses any percutient powers, he thinks magnetism, which he considers to be a simple physical action, may be successfully used as a medium for nerve vibration He reasons as follows "We do not fully appreciate the effect of subtile or subtilty forces acting on the organism

"When the so called mesmerist induces a state of hypnotism in his patient by simply blowing on the face, or when by 'passes' he impresses the retina, he acts physically on the terminal twigs of highly sensitive,—and generally educated—nerves, and induces a set of actions, which though notably in themselves, are no more mysterious in the manner of their production, than the involuntary strong muscular action excited by the tickling of a hair, or a feather, or the crawling of an insect "

He neglects, or probably ignores, to recognize how much the condition which Carpenter terms "expectant attention" has to do with "mesmeric passes," or, indeed, with any form of medication, not even excepting the percutient, for the more mysterious the method the greater is the patient's attention concentrated, and credulity exercised His reasons for considering electricity impotent to bring about this effect, will, I believe, not bear investigation

He says "That current simply uses the nerve structure as a conductor and passes along it without throwing it into vibration Electricity travels in the line of least resistance without relation to the particular tissue which offers itself as a conductor, except so far as regards its capacity for receiving and transmitting the current Electricity will pass along the tract of a nerve, taking the place of nervous energy, and itself producing the phenomona of muscular contraction, instead of eliciting nervous force from the nerve centres "

My opinion is, that we are not yet able to estimate the effects which even atmospheric electricity has upon "sensitives," or highly nervous organizations, especially when morbidly sensitive by disease The cause of results, either beneficial or deleterious from living in certain regions, has not yet been attributed wholly to the right source Why a neighborhood of 20 miles area will have cases of idiopathic asthma at the rate of ½ per cent , and why, upon going outside of that area, their asthmatic condition ceases, is yet a mystery To say "'tis something in the atmosphere," is far from solving it We know that these electrical currents have much to do with the vigor and growth of the vegetable world We know that there are diurnal tides of atmospheric electricity, this fact is equally as certain as that of the tides of the ocean, and there are also annual tides, the quantity of electricity being greatest in winter, the increase from summer to winter being gradual I believe that when these facts are more generally understood, we shall come nearer solving the question of why people living in the same climate should not be equally affected, beneficially, or otherwise, the answer being that the idiopathic conditions of some require more electricity—atmospherically—than that of others

These problems may be labelled *Psychical Phenomena* and placed among their numerous kindred, but the time is fast approaching when that term *Psychical* must have an intelligent definition and an honorable position Science is out after these so regarded "Airy nothings" and is making for them a "local habitation and a name"

That symptoms do exist in certain forms of nervous disease, which should be accredited to statical changes in the atmosphere, all scientific minds must admit Our best authors recognize this fact, especially the more modern ones, although Dr Granville does not Yet in illustration of some of these conditions, or phases which are generally ascribed to the state of the atmosphere, I can give no better description than by quoting the author himself, who, while discussing diseases of morbid irritability, and the sudden and mysterious changes which the patient presents, speaks as follows "At times an ataxic patient will walk well, at others he can scarcely stand One day he can perform almost any desired movement, while on another he can scarcely do anything in an ordinary fashion Nor is it possible to connect the variations which take place in his power of coordination with the mental, or bodily state, at least I have failed to establish any such connection Sometimes I have thought a patient more orderly in his movements when he was a little depressed, at others, when he was brightest

"Treating many cases at the same time, I have observed a tendency on the part of each, and all of them,—although not in communication, even in my waiting-rooms—to be at their worst on the same day, and have natuarally looked to the weather, or the state of the atmosphere, as regards temperature and moisture, and electrical conditions, for an explanation, yet I cannot say that I have succeeded in discovering any connection"

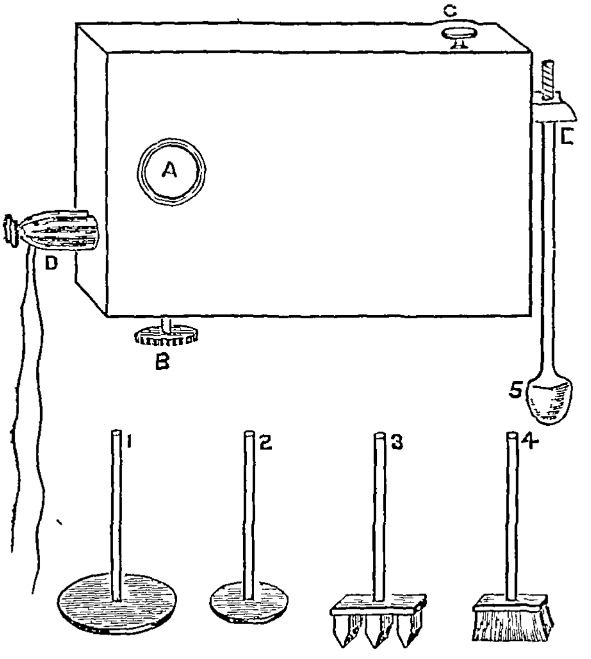
Now, although I most heartily enter into the spirit of many of the ideas of our author, yet I am not ready to cast aside everything, either in science or nature, which does not harmonize with his present state of reasoning His arbitrary way of fashioning circumstances to suit his conclusions, suggests the query, which of the two alternatives he would adopt, if by chance, he should have a case which did not yield to nerve-vibration, (or percussion) Would he dismiss the case, or would he change the treatment? Like the tailor in the story, would he make the coat to fit his man, or undertake to make the man fit the coat? Although we are continually being disappointed with the results of electricity when used in diseases of the cerebro spinal nervous system, yet I am very much of an opinion that the fault lies largely within ourselves, for we are, as yet, altogether ignorant of this agent which seems to promise so much in a large variety of ways, and is at present the foremost object of interest with scientific people

But let us return to our subject The pages which our author has devoted to the consideration of locomoter ataxy are, I consider, vastly suggestive, and hence interesting His theories that this morbid condition,—loss of coordination,—is caused by something other than loss of sensation, and his efforts to prove the same, are worthy of careful attention He says, (as showing the correctness of his conclusions), "In the course of the disease, or diseases,—for I believe there are several,—which have loss of coordination for one of their prominent symptoms, it will soon be apparent to the careful clinical observer, that the essential morbid condition is a block, or undue resistance in the course of the motor nerves The notion that loss of sensation is the primary fault may be dissipated by a simple, familiar experiment" The experiment which he mentions is, *to tell the patient to place his toe on a certain figure of the carpet, this act he will show his inability to perform, long before his foot has come in contact with the carpet* His foot will be projected out one side, or beyond the spot, because, as he says, "the patient fails to make his muscles obey his will" I cannot forbear expressing the hope that his reasoning may prove to be correct

I must be allowed here to quote the author's opinion as to the etiology of this disease, as it more fully illustrates what he would have us to understand, and then we will turn to an investigation of the instrument itself, which is to rectify these conditions —we will hope "What then, is the explanation of the etiology of Tabes which I have to submit? Briefly this I believe the disease to be at the outset a disorderly vibration of the nerve-cells, or fibres; and in the end, an arrest of vibration altogether. The first organic cause is, I think, change in the neurilemma, and in the syphilitic type of the disease, I believe the specific inflammatory action followed by deposits, extends along the course of the nerve sheaths, ascending to the centre from the chancre" I will quote no farther, as I believe I have made his theory sufficiently plain To those who may be desirous of further detail, I only recommend that they read the book

Before receiving Dr Granville's book, I had one of his instruments sent me from England This I found upon examination, to be just what the author himself had said of it—far from satisfactory It does not furnish means sufficient to bring about the ends desired In other words, to reach every phase of nerve vibration would be simply impossible to do with an instrument which permitted of no modification in its percutient or striking power This instrument suggested to me something which might be much more satisfactory This instrument he calls the "Clock-work Percuteur" because 'tis set in motion by winding up a spring inside, it consists of a simple train of cogged wheels, worked by a spring, and acting on a lever which carries an ivory hammer " This machine is in the form of a box 6 to 8 inches in length, and somewhat pointed at one end On one side is a pivot by which this inside arrangement is wound up Parallel with this is an ivory button which upon pressure keeps this hammer in motion, and on the tapering portion in front, is a button which, in an almost imperceptible degree, regulates the force, and speed of the hammer, and lastly, the hammer itself, which in this instrument is a small point of ivory, projecting about 1 16 inch from the outside, and immediately beneath the regulating button

The impossibility for this instrument to answer the requirements which an almost indefinite variety of pathological conditions would demand is quite apparent In the first place the operator is obliged to stop every two minutes and wind it up Again the force of the blow, at its best is not sufficient, (save it may be in rare instances), as in this treatment the ultimatum is to ' throw the nerve into a new state, or series of vibrations " To do this satisfactorily in all morbid conditions would require a variety of hammers and great liberty in regulation of speed and force of the blow, that is attained in the instrument shown below



A Button to set the instrument going B To regulate the force of the blow C, To regulate the rapidity of the stroke D Connects with battery E Holds hammers 1 Large disk 2 Smaller disk 3 Triple pointed hammer 4 Brush 5 Olive pointed hammer

My machine is an electro motor, similar to that used for electric bells, and the power comes from a battery of from six to ten cells It is 4¼ inches in length, 2¾ in breadth, and 2⅛ in width There are two binding-posts on the end, to connect it with the battery On one side is an ivory disk that makes the circuit by pressure, on the top of the machine is a thumb screw which regulates the vibration, and on the bottom there is also another thumb screw to regulate the power of the stroke The lever on the top runs out about ¼ of an inch, and has an aperture, in which the different hammers are held, as it is imperative that there be a variety of shapes and sizes, for I have found that each case requires a strictly individual treatment What the peculiarities of that treatment must be will have to be determined by the wit and experience of the operator I use mostly the olive-pointed hammer, the small pointed hammer, the large and small flat hammers, the oblong hammer, and the triple-pointed hammer, and occasionally, as in treating the optic centres, I use a disk

I felt that the greatest advantage my instrument possessed over Dr Granville's was, that it could be attached to any galvanic battery and thus be run by electricity, but this idea, although entirely original with me, had, I found, upon reading his book, been suggested to some other mind who probably saw the same defects in the percuteur which suggested the improvement to me So it is probable that the electrical percuteurs are in the market, and available to every physician, though I doubt if they have, as yet, been introduced into this country

The horror which our author expresses of having his method of treatment get amongst the "irregulars" can be well understood when we consider the abuse which electricity has received from this class, who have made it an object both of terror and derision

Until of late, our knowledge of the mechanism and functions of the nervous system has been both limited and unsatisfactory One after another of the theories on the treatment of nerve derangement have proved futile, thus showing very conclusively that we have not yet become sufficiently well acquainted with the construction of the instrument we are trying so hard to attune We have known a few deadly remedies, and these we have hurled at certain "symptoms" with the reckless force of ignorance, unaided by the aim of any absolute knowledge Look, for example, at our extravagant use of phosphorous, engendering conditions—as formerly prepared—more fatal than those which we hoped to remove We have been in the habit of trying remedies one after another, till finally, if the patient survives the end of the list, he is dismissed as incurable, and disappears from our medical horizon Then it is that this mistaken practitioner avails himself of the always open columns of our medical journals to show up the therapeutical short comings of this or that remedy he has so blindly employed, and if the name of the writer be sufficiently well known, the drug will be relegated for awhile to swell the number of misapplied remedies

It is commonly known that a nerve, physiologically considered, is composed of two great divisions, the first presenting the fibres, or tubes, the latter the cells, and that through these is generated "nervous force," the fibres acting as conductors, also that the nervous system is entirely distinct from all other systems of the animal organization, and that all other systems are dependent upon this one Any knowledge more definite than this is, we must admit, the exception rather than the rule, amongst the general class of physicians

But let us now turn our attention to the practical illustration of the utility of percussion as a means of cure in nerve disturbances I have recorded several cases which were treated by this method, and the results show, I think, very favorable evidence that Dr Granville's theories were not without some scientific foundation And if so, we have taken a mighty stride towards solving the hardest problem in neuro dynamics

Case 1 —Torticolis, or Wry Neck — A married woman, aged 29, of extremely nervous temperament, and suffering from mental trouble brought on by death of child Electricity had been applied by a competent person but this seemed to aggravate the case The muscles of the right side were affected This condition had existed for several months Not only the sterno mastoid, but the deeper groups of muscles were involved As the motor filaments of the pharyngial branches of the pneumogastric are derived from the spinal accessory, I directed my treatment to the base of the occipital bone, across to the upper part of the sterno mastoid, following the course of the nerve as closely as possible

The treatments were daily, and of fifteen minutes duration The percuteur was firmly held against the surface—though not pressed down—so that the whole force of the blow might be obtained Eight cells of the battery were employed, and I used the olive-pointed hammer, tracing the course of the nerve upwards and downwards, and over the clavicular portion of the trapezius muscle At the end of the first sitting, the muscles of the neck were a trifle relaxed, the patient being able to turn her head slightly, but the next day found the old condition to be almost re instated However, on going over the same treatment, I found the improvement still more marked than that on the day previous, and, to cut a long story short, the condition improved under each treatment, the deterioration between times becoming less noticeable

At the end of three weeks the patient presented no signs of wry-neck, and the corresponding muscles of the other side had regained their normal condition I varied the treatment somewhat, as the case progressed, by passing the hammer down either side of the spinous processes, pausing a moment at each The entire cerebro spinal nervous system seemed to respond favorably to this treatment, and the result was, complete restoration of health, and no inclination, so far, to any return of the torticolis

This patient had already gone through the usual list of nerve remedies I ordered that all accessory treatment should be stopped, save good nourishing food, pleasant surroundings, and all other necessary and proper hygeinic conditions

Case 2 —Anæsthesia of Right Leg —This occurred in a young man aged 18 years He complained of loss of sensation in the posterior portion of the right leg, otherwise his condition was that of perfect health The spot was about as large as my hand, and located over the belly of the biceps muscle Two winters previously he met with a fall while skating, and dates the commencement of the trouble from that time Irritating liniments, and various other external remedies, had been applied, with no other result than leaving an ugly looking surface The loss of tactile sensation was almost complete He suffered no pain There were no symptoms which showed any implication of the sciatic or its branches

I began treatment by applying the conical hammer over the affected part, my object being to vibrate the internal cutaneous branches At the fourteenth treatment the anæsthesia was entirely removed, and treatment was stopped Three weeks later the skin had regained its natural appearance

Though this condition was simply an affection brought on by injury to the afferent nerves, it might lead one to inquire what the treatment should be in case the injury extended to the branches of the sympathetic I reply, that the cutaneous may sometimes be made to act as conductors to other branches which pass more direct to the trunk of the affected nerve Perhaps this may be better understood if I quote our author, who says (while speaking of chorea) "Strive to impress the centres by percussing mixed or different nerves on that side of the surface of the limb opposite the line, or direction of the choeric movement, or, by percussing nerves through which antagonistic muscles might, if the case were a suitable one, be called into action reflexly " The folly of wandering around with the percuteur, as operators are largely in the habit of doing with electricity, will, I believe, be sufficiently apparent

Case 3 —Paralysis of Left Side, after Apoplectic Seizure —Mr B, aged 59, had hemiplegia of the left side, the result of an apoplectic attack three years before He had abandoned all hope of recovery, and came to me for treatment of the constipation only His arm and leg were perfectly limp and useless, the forearm and hand were considerably atrophied, and the sense of touch impaired His business kept him "on the road," but previous to this attack, according to his own statement, had always felt perfectly well, never suffered from neurasthenia in any form The mental faculties were unimpaired He had been what he termed "a high liver" Denied ever having had syphilis, and indeed there were no traces of it Said he had tried electricity, but I had no means of knowing whether it had been intelligently applied I took this case simply for experiment, my method of treatment, which I shall relate as briefly as possible, was as follows

Every day, at precisely the same hour, the patient was disrobed placed on a high stool, which just permitted the feet to rest upon the floor, the left arm was extended and held in a horizontal position by means of straps, then the pointed hammer was slowly moved up and down each side of the spine for thirty minutes This course was pursued for one week After that, I began the treatment by percussing the spinous processes the whole length of the spine, with the flat hammer, for twenty minutes This was kept up for one week more I now had the satisfaction of seeing a slight change, the patient could raise his arm a few inches higher after each treatment

The bowels now began to be more regular, but for increase of the peristaltic action I percussed over the perineal nerves, this accomplished the desired effect My patient could now move the foot upwards and downwards after each treatment, and had a little control over it when walking I now directed a portion of the time to treatment of the different fibres, but there is no need for further detail

The patient could, at the end of the third week, lift the foot slightly when walking, carry the hand to his head, and also button his vest with the fingers of that hand The treatment was kept up regularly for 48 days The atrophied condition of the hand and forearm was fast disappearing, and the bowels were regular

At my suggestion the treatment was postponed, and he left the city to pursue his business

Three months later he called and the improvement was still more marked, the limb could be used quite freely, although there was not much strength in it, the power of that side being about half that of the other

I think this case may be regarded as something remarkable, yet I wish one could know just what the result would have been had electricity been as carefully and scientifically employed in the place of percussion But this, of course can be ascertained only by repeated experiments Experiments which, I must add the physician will find to be quite tedious and time consuming

My reasons for so punctiliously observing the same hour for the daily treatments, was to carry out the idea of our author, who believes in the "force of habit" in nerve action, viz "One interesting fact in relation to the process of excitation by nerve vibration may be mentioned here all the movements excited by percussion of the nerves in a limb, have a tendency to be repeated"

Case 4—Exhausted Brain Power, Cerebral Neurasthenia—Mr White, a gentleman of 45 years, complained of numbness in both hands, the fingers feeling "as if they were done up in cotton," as he describes it Tactile sense was considerably impaired, was often troubled with "dizzy spells," and had become very despondent Examination of urine showed abundance of phosphates

I began by percussing over the cervical sympathetic, and treated the brachial plexus through the afferent branches for twelve days, of thirty minutes duration Then began treating the head symptoms, percussing with the flat-headed hammer the superior cervical nerves and plexuses, by going slowly around the inferior edge of the occipital bone Then, with the brush, I went very lightly over the scalp, going in a slow and methodical manner from before backwards, and from below upwards, for five minutes

At the end of twenty-nine applications the numbness had quite disappeared, and to all appearances the mental disturbance had also gone I must not neglect to mention that I insisted on a complete cessation of duties and cares, ordered a proper diet, and shower-baths And finally, ere he returned to business, he concluded to take a trip to Europe, where he is at the present writing

Case 5—Polio-myelitis Anterio Acuta, Infantile Paralysis—Blanche B, a child of 7 years, had been paralyzed in right leg since three years of age Health has been perfect The mother attributes the paralysis to sitting on the wet ground It came on in the night, accompanied by feverish symptoms All motor power in the limb was gone, the child dragging it along This limb was one-half of an inch shorter than the other, and the muscles were somewhat atrophied This case had been pronounced hopeless by two leading physicians

I had this child brought to my office daily until she had received ninety treatments I applied the hammer over the entire length of the spine, also up and down each side, the child meanwhile suspended in a sort of harness improvised for the case

At the end of the ninety days the paralysis was greatly improved, the muscles were becoming better nourished, and were fast regaining their normal condition The healthy condition of the child, and the strong constitution which it had evidently inherited from both parents, greatly lessened the difficulties in the way of restoration, whether by this process or any other

Case 6—Nervous Deafness, Tinnitus Aurium—A lad of 15, decidedly nervous diathesis, had been suffering from tinnitus aurium for nine months previous to my seeing him Had been "studying night and day"—to use his mother's words—"to pass examination" at school Was emaciated, and decidedly nervous starting violently at sudden noises, and very irritable

I ordered complete cessation from study, and had horse-back riding substituted in place of books

Treatment—I applied the large disk over the meatus auditorious externus, trusting it might act upon the membrane of the tympanum mechanically In combination with this, I percussed over the pneumogastric and sympathetic nerves, giving what I may perhaps be allowed to call "a general treatment" of the cerebro spinal centres The result was, a very complete and permanent cessation of all the head noises, and also restoration of the sense of hearing

Neuralgia—In certain forms of neuralgia I believe percussion will be found a more efficient remedy than electricity, especially in neuralgia of the branches of the fifth nerve, intercostal and cervicobrachial Much care and judgment is required in treating neuralgia by percussion, but the result, if successful, is very soon apparent in the sudden cessation of the intense pain, a most convincing proof, to the patient, of the efficiency of the agent employed

Sometimes the patient may complain of an increase of pain for the moment, due to the new series of the vibrations or waves which the percuteur is establishing, but this rapidly subsides, because, allowing the case is amenable to this form of treatment, 'The elements are compelled to fall into the same rhythmical vibration as that communicated to their sheath by the regular beat of the percuteur, the discord between the nerve elements and their sheath, which is the cause of the pain, and the sensation subsiding together" This makes apparent the object of the treatment, which is to establish a harmony, a rhythm of vibrations between the nerve and its sheath.

The patient should be instructed to speak the moment the pain ceases, and the hammer should be at once removed. If the pain returns within a few minutes, repeat the operation.

In the sharp forms of pain the percussion should be slow, for reasons which I trust have been made sufficiently obvious. If impossible to hit the part of the branch which the pain indicates is the portion affected, it must be approached in a circuitous manner by taking some terminal twig, but the aim of the operator should always be to approach the spot affected in the most direct manner possible. "The point to remember is, that it is with the nerve we have to deal, not with its surroundings," And that "It is useless vibrating over a nerve or centre, unless we can reach it (the nerve)." I submit the following case as illustrating my manner of procedure.

Case 7.—Cervico-Brachial Neuralgia.—Charles B., aged 33, cutter in a tailoring establishment, came to me suffering intense pain in the right arm, the pain extending from the back of the neck to the ends of the fingers, which were swollen and drawn towards the palms of the hand. The surface of the arm, over the brachial muscle, was exceedingly sensitive and cold to the touch. He had consulted a physician who pronounced it muscular rheumatism, and gave him large doses of salicylic acid, quinine, and also used electricity. The electricity caused intense pain, he said, making it "a great deal worse every time it was applied." I do not, of course, know how strong a current was employed, but it is evident the nerve vibrations were augmented rather than diminished. Indeed, I doubt if electricity, as at present understood, does not always have this effect. If this is the case, we then have a solution for the secret of the general failure of electricity in instances where the nerve vibration requires to be *subdued* rather than increased, as in facial neuralgia, and in fact all neuralgic affections of the cranial nerves.

Upon passing the hard brush over the surface, from the fingers upwards, the patient complained of pain as I reached the affected portions of the nerve, the sensitive spots corresponding to the parts supplied by the lower cervical nerves, or regions which are innervated by the sensory branches of the brachial plexus. I used the disk very lightly over these parts, and on the tender spots of the cervical vertebræ, for ten minutes duration, during which time I made two interruptions in response to his declaration that the pain had ceased, for the time being.

In six treatments the painful condition was entirely removed. He resumed labor in twelve days from time of first application. I consider the cure due to my being able to overpower the tumultuous vibration of the nerve elements within their sheath "by communicating an independent and different vibratile motion to the nerve as a whole." I think nerve vibration may also be valuable as an aid in diagnosing the exact locality or seat of nerve disturbance. By passing the pointed hammer along the limb, a reflex action commences as it passes over a morbid nerve. In this way disturbance may be traced from the branches to their trunks, and thence to the spinal cord.

Case 8.—Facial Spasm without Pain.—A gentleman, aged 27, dry goods salesman, had been troubled with spasm of the face, in the region of the buccinator, risorius, and depressor anguli oris muscles. When under excitement the spasms were constant, at other times, when the mind was in repose, the face would be quiet for several minutes at a time. Had used electricity without benefit.

I applied the brush over the terminal twigs of the facial nerve, and kept the percussion up until all tendency to spasm, for the time being, had ceased. The attacks grew less frequent between the treatments, and at the end of fourteen applications, had ceased altogether.

This was a case of several years' standing, and one of great interest to me, as I have heretofore found spasms of this nature very obstinate to overcome.

Case 9.—Chronic Anterior Poliomyelitis.—A gentleman, 38 years of age, was taken, about eighteen months previous to my seeing him, with pains in the left forearm. He applied various remedies, as for rheumatism. The same symptoms soon after appeared in the left leg, then the right leg became similarly affected. The muscles were sore on pressure, and wasting began to show itself. The sensory nerves were not implicated, the sphincters were normal, and brain power unimpaired. When I saw him, there was marked paresis in both legs, and the muscles of the left hand and forearm were considerably atrophied.

My course of treatment in this case was very much the same as that I should have pursued with electricity, viz.: To affect the spinal nerves I applied the hammer up the spine, and on each side of the spinous processes. For reflex irritation I passed the flat hammer over the sensory nerves of the legs and arms, punctiliously observing the same hour for the daily operation which I had observed in the cases preceding this.

The paresis began to disappear after he had received daily treatment for two weeks, and the muscles began to round out. He came every day for three months, at that time the paralysis was quite gone, and treatment was suspended. He continued to improve, and to-day he is, to all appearances, a well man. No internal remedies were given, but some changes were made in hygienic conditions.

Locomotor Ataxia.—Our author has devoted considerable space to the consideration of diseases of induration of the posterior column of the cord, diseases which have for their symptoms pronounced disturbances of the locomotory functions, and defects in coordination and sensation. His theories on the phenomenon of loss of coordination may be condensed in the quotation of two or three lines. He says: "... it will soon be apparent to the careful clinical observer, that the essential morbid condition is a block, or undue resistance in the course of the motor nerves."

He scoffs at the "notion" that the loss of sensation is the first, or "primary fault." He says that "the patient fails to make his muscles obey his will."

And again "Only certain muscles will be strongly energized, though the will is acting powerfully, and the endeavor to touch the object be maintained for a time," etc, etc Every year multiplies cases of diseases of the spinal cord, and with this constant spectacle before our eyes, we cannot fail to be interested in any theory which may lead to the solution of the trouble, or give a suggestion as to the method of treatment The following I consider to be a typical case of locomotor ataxy, as well as showing the method to be pursued when treating this condition by percussion

Case 10—Mr H B G, a married man, aged 43, of regular habits, no traces of syphilis, business, a salesman in a large boot and shoe store When first seen by me, he had become unable to stand erect and walk straight, and wholly unable to retain his equilibrium with eyes closed The first symptoms appeared three years previous with pains in the lumbar region of spinal cord, and trembling in limbs when stooping He feared kidney trouble Shortly after this, one cold morning, after a long walk to the store, he experienced pain in the heel and bottom of left foot, this condition soon made its appearance in the other foot, and he put lamb's wool soles in his boots to protect the bottom of the feet The pain soon extended up the legs and thighs, and he now consulted a doctor, who prescribed syrup of triple phosphates, with stimulating liniments to the limbs He now noticed that he "scuffed" when he walked, and took out the in soles, his feet feeling already terribly "muffled up," to use his language The first symptoms he noticed of "anything wrong" was when, in ascending the short step ladder used in these stores, for the purpose of removing a box of shoes from a high shelf, he could not retain his equilibrium, and a horrible sensation of helplessness possessed him

The objective features of this case are those to be ordinarily found in diseases which have induration of the posterior column of the spinal cord with one exception, viz His hair (of dark color) was white in spots of about the size of a silver dollar, appearing in quite regular order over the entire head These, he tells me, began to appear with the pains in the lumbar region How much, or how little they were connected with the diseased condition, is of minor importance here

My treatment began by ordering complete cessation from business, perfect regimen and hygienic conditions I stopped all internal remedies, and began daily applications over the spine, and along the sides of the column For the hindrance in locomotion I treated the irritable nerves with a light blow fifteen minutes every day, to arrest the disorderly or abnormal vibrations of the nerve cells, and establish a normal condition, after our author, who says

"I believe the disease to be at the outset, a disorderly vibration of the nerve cells, or fibres, and in the end, an arrest of vibration altogether"

"In short, I believe the cause of the malady to be a disturbance of that orderly vibration which is essential to nerve action and function, whether in the posterior, lateral or anterior columns of the cord, or in the nerves that transmit impressions from the periphery, or carry down motor impulses from the centre to the muscles" Of the efficacy of nerve vibration in this condition, he says "It controls the disorder, changes the state, and helps to reestablish that mobility of the nervous elements which is essential to health"

I began my work upon this subject just thirteen weeks ago, and he is still under my care At the present time of writing, the indications are certainly encouraging He has almost completely overcome the locomotory disturbance, and, unless something unforeseen interferes, I hope to be able to reestablish perfect harmony of action in the power of co ordination

I have selected the foregoing cases from a much larger number, as best serving to show the results when treatment by percussion alone has been employed Yet I do not know that I can, in truth, say that this has been the only means employed for I have in every instance insisted upon correct hygienic conditions, such as diet, clothing, air, exercise, cleanliness, sleep, and morals

The majority of the cases cited have been of a high and intellectual class, ready and anxious to follow directions, which—it need not be said—is a very powerful auxiliary to any form of treatment What the result in these cases might have been, had some of the older and better known remedies have been used in its stead, of course we cannot tell Several of the patients had used electricity, they told me, but it had been applied either by themselves or by some one equally incompetent It must be admitted that the cases I have cited speak very flatteringly for this method, but many failures are likely to come between these and their duplicates I might record a number of instances where percussion was used in combination with internal remedies, but this would not answer the desired object We want proof of the correctness of our author's theories

If my opinion were asked as to the efficiency of percussion in diseases of the cerebro spinal nervous system, I should say that, like every other remedy, it is subject largely to conditions Like electricity, it may succeed beautifully at one time, and utterly fail the next All other conditions being equal for this form of treatment, it will then be impotent unless handled with exquisite care and skill Failure must inevitably follow if the manner of its application be faulty, hence, however great its possibilities, I fear it can never be an universally popular remedy The physician who employs percussion in the treatment of his patients must "take no note of time," and possess an inexhaustible amount of patience It cannot, like massage or electricity, be passed over to an assistant The percuteur must be in the hand of him who not only is thoroughly familiar with the anatomy of the nervous system, but who also understands the pathological condition of the patient At present we know too little of disease, or its remedies, to throw away uninvestigated any theories which have anything like a scientific basis, as Percussion surely *seems* to have

While our author's idea that percussion is *all* that is required in diseases of the cerebro spinal nervous system may seem illusory, the *test rests with every physician who makes diseases of the nervous system a specialty*

GEOGRAPHICAL PATHOLOGY OF CONSUMPTION

BY G W McCASKEY, A M, M D,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST FT WAYNE COLLEGE OF MEDICINE FT WAYNE IND

III

Altitude —The question of altitude in its relation to phthisis is one of the gravest importance, and has been occupying for some time a large share of the attention of medical writers Treated in accordance with the plan of these papers, of course only the most general deductions can be made If it can be shown, however, that the mortality from the disease at different altitudes is so conflicting as to render a formulated law quite impossible, and make it necessary to study the special indications of each case, an important object will have been attained No greater calamity can befall the advancing study of the climatic treatment of consumption, than the routine habit, so much in vogue, of sending patients to certain localities without determining their special fitness for each case

In the United States every degree of elevation can be found, from certain parts of the coast line which are not more than fifty or one hundred feet above sea level, to the highest habitable limits Along the Atlantic and Gulf Coast line we have a belt of varying width which is less than four hundred feet high At such a low level of course no comparison can be made with high altitudes as forming with them a continuous series, for the investigations of Muller have shown that in descending from mountain elevations towards the plains, the maximum degree of mortality from phthisis is reached at a heigth of from 650 to 1650 feet Below this level, therefore, we may assume that variations are not of much importance, so far at least, as barometric pressure is concerned But along this level belt above referred to, we observe every degree of mortality from consumption found in the United States, from its very highest to about its lowest It is also worth noting that the highest mortality is generally found where its elevation is greatest, and the lowest where it is least These facts are at variance with the oft repeated statement that consumption is necessarily more prevalent in regions near the level of the sea The territory and population involved are so extensive that it can not be considered an exception, dependent upon accidental local conditions

The region comprising New Mexico, Arizona, Colorado, Utah, Wyoming and Nevada, lies at an elevation of from 4,000 to 8,000 feet These states and territories have individually and collectively, the lowest death rate from consumption in the United States, differing but little, however, from some parts of the Gulf Coast, almost at sea level

The group of states from Kansas to Minnesota is about one half as high as the last named region, and has a mortality from consumption nearly twice as great The section of Ohio bordering upon the Ohio river is from 800 to 2,000 feet high, 15 9 per cent of all deaths are due to consumption The lake counties are from 400 to 800 feet high, only 11 2 per cent of all deaths are due to this disease—nearly 30 per cent less than in the more elevated regions Many other facts, incompatable with any possible law except the diminishing prevalence of consumption at high altitudes, might easily be cited

Ruehle says that an elevated position protects from phthisis, but that it must be at least 1,800 or 2 000 feet high That elevation does not protect is conclusively shown by the facts presented Especially by the fact that in Colorado, which is more than 4,000 feet high, more than 8 per cent of all deaths are due to consumption It seems needless to remark that the assertion of Prof F T Roberts that regions situated at a low level present a large number of cases, is altogether too sweeping That consumption is rare in most elevated regions is a fact That these regions, however elevated, within ordinarily habitable limits, confer complete immunity, is not a fact And finally, that the degree of elevation, has an intrinsic relation to the prevalence of the disease is a view that finds no support in the facts which have been presented

The reason why phthisis is rare in elevated regions is not known Niemeyer says distinctly and frankly that it is "without apparent reason" Ruehle says that it is not determined if it is due to low barometric pressure, but that it may be due to purity of air The facts cited by Herman Weber, in his recent Croonian lectures, regarding the number of organisms in the air at different elevations (Tyndall, Pasteur, and others), lends great weight to the latter surmise

Occupation —The question of occupation in its relation to consumption suggests a few facts to which attention may be called For our present purpose we may omit those occupations included in the class designated as professional and personal services, and trade and transportation A little more than one-fourth of all those who have a specified occupation belong to this class Their mode of living and sanitary surroundings are too diverse for analysis The two remaining classes include those engaged in agricultural pursuits, and those engaged in mechanical and mining industries

We will consider the occupations of some of the states in their bearing upon the mortality from consumption, taking as a basis the percentage of those in the second class—manufacturing, mining, etc —to the entire number of those who have a specified occupation Of course it is generally supposed that the occupations included in the second class, with some few exceptions, favor the development of phthsis In the United States about 22 per cent of all those who have an occupation belong to this class When we come to examine the different groups of states we find, what of course was already matter of common knowledge, the major part of our manufacturing interests in the New England and middle states In New England 42 per cent, and in the middle states 43 per cent of all those who have a specified occupation belong to this class, comprising manufacturing, mechanical, and mining industries In the South Atlantic and Gulf states there are but 4 7 per cent, while in the interior and lake states there are 16 6 per cent in the same class Now it so happens that in these different groups of states their sequence when arranged in the order of their manufacturing importance as thus determined, is the same as when arranged in the order of greatest mortality from consumption, with the exception of the New England and middle states But among the individual states forming these groups, the most marked discrepancies are found Practically the same death-rate from consumption is frequently found in different states with manufacturing interests widely variant or *vice versâ*

Arkansas and Tennessee have only 4 per cent and 8 per cent respectively in this class, but their death rate per 1,000 from consumption (1 2 in Arkansas, and 2 4 in Tennessee) is 6 lower in the former, and 6 higher in the latter than the average for these states Tennessee has a smaller percentage of people in this class of pursuits than Florida, while its death rate from consumption is about 2 5 times as great In the remaining States the proportion of this class varies from 12 per cent in Kentucky as the lowest, to 26 per cent in Maryland as the highest There are fourteen States in this section and seven of these are above the average (16 6 per cent) and seven are below it

In the following table the Interior and Lake States are arranged in sub groups, the first containing those above the second those below the average, with consumption death rate for 1880

INTERIOR AND LAKE STATES—GROUP 1

States in which percentage is above average (16 6)

	Percentage of those in manufacturing etc	Deaths per 100 from Consumption 1880
Maryland	26	2 5
Ohio	24	1 9
Indiana	17	2 0
Missouri	17	1 5
Illinois	21	1 5
Wisconsin	20	1 3
Michigan	23	1 6

GROUP 2

States in which percentage is less than average (16 6)

Virginia	13	2 0
West Virginia	15	1 6
Kentucky	12	2 3
Tennessee	8	2 4
Arkansas	4	1 2
Iowa	13	1 2
Minnesota	15	1 1

It will be difficult, I think, from a study of this table, to find support for the view that those engaged in manufacturing, mining, and mechanical industries are more liable to consumption than the class following agricultural pursuits In the sub group containing those States below the average there are three States with a death-rate from consumption above 2 0 per 1,000, while in the other group there are but two On the other hand, geographical distribution will be found to be apparently a much more important factor For example, all States in this group west of the Mississippi river have a death rate from *consumption of less than 1 5 per 1,000, while in all* those east of this river, with one exception (Wisconsin), it is 1 5 or more

In the Middle States the figures fail to furnish any support to the theory, 43 per cent of those with occupations are in the class we are considering New York has 53 per cent with a death-rate of 2 5—both of which figures happen to be the highest in this group But in Delaware, in which the percentage is only 26—less than one-half what it is in New York—the death rate is about the same Pennsylvania has proportionately about 40 per cent more people engaged in these occupations than Delaware, but its death-rate is about 21 per cent less In New Jersey it is 40 per cent, and the death-rate 2 3 per thousand

In the New England States the death-rate from consumption only varies from 2 2 in Connecticut to 2 9 in Massachusetts, while the percentage of those engaged in these occupations to all persons of specified occupations, varies from 19 per cent in Vermont to 57 per cent in Rhode Island Here, again, as in the Middle States, the highest figures correspond But Vermont, with its lowest percentage (19), has precisely the same death rate (2 4) as Rhode Island, with its highest percentage (57), while Connecticut, with 47 per cent engaged in these occupations, has the lowest death rate from consumption in New England The death rate in Rhode Island, with 57 per cent, is precisely the same as in Tennessee, with 8 per cent These figures show, if figures can show anything, that if occupation has much to do with the mortality from consumption, it is completely masked by other and perhaps unknown conditions

These remarks do not apply, of course, to certain occupations in which the inhalation of irritating particles or gases might *readily produce conditions pre*disposing to consumption My only object has been to show the general effect of occupation upon the prevalence of the disease as indicated by its mortality

The action of a "cold" in producing a "catarrh," which is followed by phthisis, is not sufficiently prominent in studying this question Those engaged in agricultural pursuits are greatly exposed to the vicissitudes of the weather, and while their out of door life is in itself certainly conducive to a vigorous state of health, it may be seriously asked whether the consequences of repeated exposures may not in great measure offset the ill effect produced by the unsanitary conditions of factory life

In making a statistical study of the various climatic and other conditions found in the United States, in their relation to consumption, the object has been to study the subject on an extensive scale, leaving out minor details almost entirely Not because minor details are unimportant, but because their detailed study is quite incompatible with a gen eral survey. Not only so, but individual localities often present anomalies which set at defiance all known laws of health and disease.

The following facts, which furnish a forcible illustration of the contradictory results obtained by a detailed study of local conditions, are quoted from Dr. Andrews' Lumleian Lectures of the Royal College of Surgeons, of England, last year. In 1866 Mr. G. A. Rowell, of Oxford, published a pamphlet "On the Effects of Elevation and Floods on Health." He was a man of deservedly high local reputation, spent immense labor on his task, and his facts, remarkable as many of them are, are probably trustworthy. Unfortunately their verification is extremely difficult, for he compares single parishes and small districts which it is impossible to pick out of the Registrar General's tables. Here is his account of two villages a few miles from Oxford, up the Thames valley, given with some verbal alterations and omissions of unimportant details.

"Cassington and Wolvercot are both situated on gravel, both have excellent water for drinking purposes, and both are in the same poor-law union, and within two or three miles of each other. Cassington is not situated on a hill, but upon a bed of gravel, which projects into the valley towards the river, but is high and dry above it. The village is fully exposed to the currents of air which sweep through the valley from west to east, having but little protection from trees or other shelter. The roads through the village are wide and well kept, the cottages appear to be much better than in most villages, are well distributed, and although I saw it in wet weather, during a flood season, I thought it one of the cleanest villages in the neighborhood. Wolvercot presents appearances as reverse as possible to those of Cassington. It is protected from the east wind, and Lower Wolvercot is well sheltered by trees on the north and north east. Along the bottom of the rising ground in Upper Wolvercot there is a ditch of stagnant water, and the ground between the lower houses and the canal is liable to flood in winter, presenting at all times the nearest approach to a swamp that I know of in the Oxford valley. In Lower Wolvercot some of the houses are at times flooded, and all of them are but little above high level. There are stagnant ditches around the village and stagnant pools within it, except in dry summer time; even the road through the village, till very recently, was generally impassable for carts in flood seasons, and partially flooded at all times. The cottages certainly are not better than they are at Cassington, while they are much more crowded together. At Wolvercot a great many ducks and geese are bred, and the early broods in cold spring seasons are often kept within doors in the cottages. Thus, in accordance with general opinion, the condition of Wolvercot is much less favorable to health than that of Cassington, but statistics for the twenty years from 1841 to 1860 show that in Cassington the death rate was 27 per cent. higher than in Wolvercot, and the average of life 25 per cent. in favor of the latter village also." The actual figures given by Mr. Rowell are as follows:

Cassington	Annual deaths, 1 in 40.2 persons	Average Age, 25 years, 10 months
Wolvercot	Annual deaths, 1 in 51.3 persons	Average age, 31 years, 7 months

"Allowing for the difference in the population of the two villages, more than double the number of deaths from consumption occurred in Cassington than there were in Wolvercot. Classing that disease with all others of the respiratory organs, the deaths were 70 per cent. in excess in Cassington."

Such anomalies as those presented by Cassington and Wolvercot have been observed again and again by almost every medical man. Single houses, and sections of cities, apparently the most unsanitary, have exceptionally shown an excellent health record for their inhabitants, and *vice versâ*. Because of such anomalous facts as these, the reason for which cannot in the present condition of our knowledge be explained, it seems clear that a general average, even at the expense of slight inaccuracies, is much the safest basis upon which to predicate a general law.

It may now be asked what conclusions can be drawn from the facts presented. These have been for the most part given each in its proper place, and little more is here required than their restatement, which may thus be summarized, viz.: That the mortality from consumption, and we may add its etiology are not esentially dependent upon temperature, altitude, hygrometric conditions, or coast influences. That these factors, singly and in combination, have a considerable influence against or in favor of the development of the disease is probable. But it is generally a matter of doubt how much is due to these and how much to unassignable conditions. While consumption is generally rare in regions with low temperature, it may be equally rare in regions with the highest temperature found in the United States. While it is rare (but by no means always absent) in regions above 4,000 feet high, it may be equally rare in regions less than fifty feet high. While it is generally rare in a dry atmosphere, it may be equally rare in an atmosphere saturated with moisture, *unless associated with a low temperature*. The highest and almost the lowest mortalities are to be found on the Atlantic coast, showing together with other facts, that coast influences, unless masked by unknown conditions, are neither essential for nor against.

These conclusions, which savor strongly of medical agnosticism, seem to be for the most part, in accord with Ruehle, who says: "The investigations of Hirsch have shown that neither the geographical position nor the temperature of a region have any thing to do with the prevalence of consumption. * * While rare in Iceland, the island of Marstrund, Steppes of Kirghis, interior of Egypt, plateaus of Mexico, Costa Rica, and Peru, and in the interior of South Africa, it is common in Sweden, as well as in India, in Siberia, Australia, and South America." He thinks, however, that moist air favors consumption, especially when the temperature is continually high—a view which it is needless to say is diametrically opposed to the facts presented.

It is not intended to underrate the value of the climatic treatment of pulmonary phthisis, but rather to show that neither the immunity from the disease, nor its prevalence can be shown to be uniformly, or even generally associated with any one combination of climatic conditions. We must, indeed, admit that the peculiar climatic conditions which confer a relative immunity are in most cases unknown. So contradictory are the climatic conditions associated with different phthisis mortalities that one may reasonably doubt whether the results are directly due to the climate *per se*. Jaccoud, in answer to the question "Has climate of any kind a curative effect upon tubercle?" says "No, the answer is unreservedly negative. It is therefore useless to inquire which climates have this effect to the fullest extent, since in no case does such influence exist." Nevertheless, there are certain indications to meet in each case. Dr. Herman Weber, in his recent Croonian lectures, *thus summarizes these indications*: "The difference between different cases of phthisis is so great that it is impossible to lay down fixed rules for climatic treatment. In deciding between different climates and localities, the circumstances connected with the etiology, the stage of the disease, the amount of destruction, and the complications with diseases of other organs, are important, but still more so the distinction between a weak and a strong constitution, an excitable or a torpid nature—between progressive and retrogressive active or stationary cases. Mental peculiarities ought not to be overlooked, nor the habits of the invalid and the circumstances in which he has lived." But whether the reasons are in all cases apparent or not, we may continue to benefit our patients by sending them to regions where consumption is rare, and where experience has shown that certain classes of cases are benefited.

The *causa sine qua non* of consumption is of course outside the scope of this paper. It may not be out of place to remark, however, that the total lack of all essential relation to climatic conditions, so clearly shown, is a strong, though perhaps superfluous negative argument in favor of its specific origin. The parasitic nature of the disease, to which tradition and clinical history so long pointed with prophetic finger, has at last been conclusively demonstrated. The pathogenetic relation of Koch's tubercle bacillus is established. Around this great central fact all etiological, pathological, diagnostic, clinical, and therapeutical theories will hereafter rotate. The broad facts of its geographical distribution, so often apparently meaningless and contradictory, will ultimately find in the sequelæ of this discovery as complete a solution as they are capable of receiving. It will then be found that those climatic conditions which confer a relative immunity are just such as will, by invigorating the system, raise the tissues to the highest degree of what has been called their "bactericidal power." Preventive medicine, in dealing with phthisis, will have to look for the solution of its problems in the direction of germicidal agents and conditions. In short, the whole literature of phthisis will have to be, and even now is being reconstructed in the light of this great discovery.

THE TREATMENT OF PULMONARY DISEASES BY MEANS OF "PNEUMATIC DIFFERENTIATION"[1]

BY VINCENT Y. BOWDITCH,

OF BOSTON.

It is my purpose to speak of a new method of treatment for pulmonary disease, which was brought to my notice not long since in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, February 14, 1885, in which the writer referred to an article in the *New York Medical Record* of January 17, 1885, by Dr. Herbert F. Williams, of Brooklyn, New York, who speaks of the "Antiseptic Treatment of Pulmonary Diseases by means of Pneumatic Differentiation," and records with their results a series of cases which have undergone this method of treatment.

I speak of it as a new method, because I believe it to be a step forward in the treatment of one of the most formidable diseases with which we have to contend, and whatever may be the results of future investigations, I deem it worthy of the careful consideration of all members of the regular profession, and if the results are not what we have been led to hope for, we can, at least, say that no harm has been done by our endeavor to find a new weapon against a terrible disease.

The treatment of pulmonary diseases by the inhalation of compressed and rarefied air has been for several years used by well known scientific men with apparent success in many cases in Europe, especially in Germany, and to a much greater extent than in our own country, where I think I am right in saying that comparatively little attention has been paid to either method by members of the regular profession. Various irregular practitioners have used inventions of their own, having more or less similarity to each other, for the disease in question, but whether from the fact that such people usually keep their inventions to themselves, or because they have been proved to be utterly worthless, no marked movement toward a general adoption of such therapeutic measures has been made.

It has been my good fortune in studying the subject to come across the methods of treatment of one or two irregular practitioners, which at first seemed to resemble closely that adopted by Dr. Williams, but which upon closer examination were found to differ in essential points. Of these methods I shall speak more fully later.

The treatment of pulmonary diseases by means of compressed and rarefied air, as used in Europe, is meant chiefly to accomplish the same result as removal to some different section of the country where the air has the requisite degree of density or rarefaction for the treatment of the disease in question. To obtain this, air-tight compartments are constructed, in which the patient sits for a given time, and the air is then partially exhausted or compressed, according to the needs of the case, which treatment is continued for a certain number of hours in the day for several weeks, or possibly months, and the results seem to justify the fact that these methods are in constant use in Europe[1] Various portable instruments have been devised by different scientific men for inhalation of compressed air, and *vice versa*, the best known being the apparatus of Waldenburg, of Tobeld, of Schnitzler, or of Geigel and Meyer, also another of J Solis Cohen,[2] of Philadelphia, all being modifications of the same idea, illustrations of which I shall show you to night, as seen in books upon the subject It will be noticed that in the use of these last-mentioned instruments the surface of the body is exposed to the ordinary atmospheric pressure, whereas in the case of the pneumatic chambers the atmospheric pressure upon the body and in the lungs is increased or diminished according as the air in the cabinet is compressed or rarefied

---

[1] Read before the Section for Clinical Medicine Pathology and Hygiene of the Suffolk District Medical Society May 13 1885.

Still another method has been invented by Hauke, called by him the "Warme," or tub, spoken of in Ziemssen's "Handbuch der allgemeinen Therapie," but as far as I can discover, the apparatus has not been universally used In following out this method, a rubber hood, closely fitting about the head and leaving the face only exposed, comes down over the shoulders like a shirt The patient is then made to lie down in the "Warme," which in shape resembles a tub, having a close-fitting rubber cover which encircles the neck of the patient, and the hood is then fastened to the edge of the cover by means of an elastic band The air is then partially exhausted from the interior of the 'Warme, which decreases the atmospheric pressure over the surface of the body, with the exception of the face Upon inspiration the increased pressure of the outside atmosphere materially tends to expand the lungs from within, and the inspiratory act is greatly facilitated, whereas the expiratory act is proportionately increased, and a calisthenic action of the lungs and chest walls is thereby obtained to a greater degree than by the ordinary respiratory movements

A similar method to this was adopted by an irregular practitioner, entitled "The Hadfield Body Receiver for the New Haven Vacuum Cure," used, I have been informed, in 1869, a sketch of which I have with me

I have mentioned quite superficially the various methods used by the regular profession in so called pneumatic therapeutics, so far as I have been able to learn of them, that you may be able to understand the general principles of their use, and before speaking of Dr Williams's cabinet it is only necessary to mention the various methods of inhalation familiar to us all, used all over the world in the treatment of pulmonary diseases, for example, inhalations of atomized sprays of different substances, of the use of rooms filled with medicated vapors, etc , all of them seeming to have met with more or less success, but too numerous to do more than mention here as they bear upon Dr Williams's method of treatment

In March, feeling much interested in what I had read of the Pneumatic Cabinet, I went to Brooklyn and was there enabled, through the courtesy of Dr Williams, to study the apparatus thoroughly, and to examine three or four of his cases which had derived marked benefit from the use of the so called differentiator The cabinet is made of iron, and resembles a large iron safe in general shape, in one end of which is a large, thick glass window It is between six and seven feet high, about three feet wide, and from three and one-half to four feet long, in short, large enough for a man or woman to stand up or sit down in comfortably Opposite the window is a heavy iron door edged with rubber and furnished with heavy bolts, all moved easily by one handle, so that the door can be instantly opened Beneath the window is a projection in the side of the cabinet to accomodate the patient's knees when sitting with the face near the window, the same projection serving on the outside as a shelf upon which the atomizer used with the apparatus is placed Passing through the glass window is fixed a short gutta-percha tube about one and one-half inches in diameter, having a stop cock on the outside, and ending in a trumpet-shaped opening for receiving the spray, the inner end being fitted with a movable rubber tube and mouth-piece for the patient's use Near the cabinet stands a cylindrical iron vessel, from which the air is as nearly as possible exhausted, communicating with the interior of the cabinet by means of a pipe and stop cock A barometer, connected with the inside of the cabinet to show the amount of rarefaction of air in the interior, is fastened to the outside of the cabinet

The patient enters the apparatus, seats himself opposite the window, the door is closed and the stop cock of the pipe connected with the vacuum is opened The air from the cabinet rushes to the vacuum, and when the barometer shows a depression of two tenths of an inch the stop cock is again closed A spray, usually of carbolic acid, iodine, iodoform, or bichloride of mercury, either singly or in combination with each other, is then put in front of the inhaling pipe, the patient is directed to insert the end of the tube in his mouth, closing the lips over the mouthpiece, at the same time compressing the nostrils with his fingers to prevent the air rushing out through his nose, the stop-cock is turned and the outside air rushes in, carrying with it the medicated spray and causing a more forcible involuntary inspiration, giving one the sensation of having taken an unusally full, deep inspiration, the patient then, by a voluntary forced expiration, exhales through the tube again, and continues these respiratory movements several times Upon the least feeling of fatigue the stop-cock is turned and the patient, after removing the tube from his mouth, breathes the rarefied air of the cabinet again until ready for a second trial The time occupied in this treatment varies from ten to thirty minutes, and usually daily applications are made, the greatest number given, according to Dr Williams's pamphlet, being one hundred and thirty-five The amount of rarefaction used in the beginning is never more than what would cause one tenth or two tenths of an inch depression of the mercury, but during the treatment a gradual increase of rarefaction may be used, up to an amount causing a one inch depression of the mercury, although in many cases, doubtless, even a greater degree of rarefaction could be used with benefit and without evil results

---

[1] Compartments of this nature exist in Lyons Montpelier Nice Stockholm London and St Petersburg also in several places in Germany but I am not aware that any similar chambers are constructed in this country They are expensive and need the care of experienced persons in the regulation of the various devices used in connection with them and it is probably for this reason that they are not more universally used

[2] Solis Cohen s article in New York Medical Journal for October 18 1884 entitled Compressed and Rarefied Air as a Substitute for Change of Climate

The only peculiar sensation which may be noticed in the beginning of the treatment is a slight crackling in the ears, as the air is being exhausted from the cabinet, but if the patient be told to swallow two or three times, this symptom will entirely disappear

It will be seen, I think, from the foregoing description of the apparatus that what it accomplishes is twofold in its nature, namely it produces a much greater expansion of the lungs than is possible by an ordinary full inspiration, and, at the same time, the medicated spray being carried with much greater force than by a natural inspiration is deposited in the deeper portions of the lungs in a much more thorough manner than by any other method that I know of, as has been proved satisfactorily by Dr Williams in a series of experiments referred to in his pamphlet

As to the principle of his cabinet, it will be noticed that it resembles in theory the "Warme," or tub, of Hauke, before mentioned, in which atmospheric pressure on the surface of the body is lessened, the face only being exposed to the outside air, but the simplicity of Dr Williams's method, by which the patient is enabled to undergo the process without the discomfort of putting on extra coverings, as in Hauke's plan, will strike every one, to say nothing of the greater thoroughness with which the purpose is accomplished The chief merit of his cabinet lies, however, in the fact of the *combination* of the medicated spray with which the increased strength of the inspiratory movements For full accounts of his cases which have undergone this treatment I must refer you to his pamphlet, merely remarking that the percentage of cases which have improved is most gratifyingly large and that it must be left to the future to determine whether others meet with equally happy results I wish to speak, however, of three patients whom Dr Williams kindly let me examine [Cases I, II, and IV, were read from Dr Williams's pamphlet]

Upon examination of case 2 of Dr Williams's pamphlet, I found him to be a young man of rather delicate build, but otherwise looking well, and to all outward appearances in good health Percussion of the right chest showed slight dulness in that region, and upon auscultation a faint crumple was heard, and the respiratory murmur was harsh, but the gurgling sound and the amphoric quality spoken of at the first examination I did not get The young man spoke of himself as feeling all right, but upon closely questioning him I found that he had a slight cough upon arising in the morning Of the evident marked improvement from his previous condition as described, no one would doubt, he had been able to resume his work a year previous

CASE 1 (a young lady), when I saw her, looked rather pale and anæmic, but her mother spoke to me especially of the condition in which her daughter was before beginning the treatment, and of her belief that she was well Examination of right chest showed dulness and crumpling with inspiration,—a marked difference from the signs noticed before,—and the patient was able to do, as far as I could learn, every thing that the other members of the family were accustomed to

CASE 4, which was complicated with empyema, looked perfectly well, showing a slight fistula in the left chest Upon examination, all the signs of a former empyema on the left side were present Dr Williams also spoke of the presence of a slight crumple, heard at one time under the right clavicle in the course of the disease, but after the continued use of the cabinet it disappeared, and when I examined him the inspiration was absolutely pure at that point

In regard to the first two cases it should be said that Dr Williams does not wish to claim that they are insured against a return of the trouble on the contrary he thinks that they both will eventually die of phthisis, but he does claim the greatest improvement and an arrest of the disease, and, as far as outward appearances are concerned, a return to health He hopes for the greatest benefit to arise in those cases of incipient phthisis where there seems to be nothing more than a catarrhal condition of the lung, and his one desire is that his method of practice shall be given a fair trial by members of the regular profession everywhere In those cases, moreover, of a slowly expanding lung after pleuritic effusion, the mere mechanical treatment of the cabinet can be of great assistance in promoting expansion

In every collection of cases of this sort, it is only right that we should carefully weigh every evidence for and against the justice of the conclusions drawn In the cases enumerated in Dr Williams's pamphlet we must think of the moral effect of the new method upon the patient No doctor is unaware of the marvelous influence which the mind has over the body, and of the marked improvement which often takes place in the general condition of a patient upon trying a new physician or a new method of treatment We must think, moreover, of the possibility of the enthusiasm of the inventor blinding his eyes to certain facts which must be considered, while wishing at the same time to be perfectly fair and unbiased in his statements, we must also not be too greatly influenced by the delight of friends and relatives, who, seeing a marked improvement in one dear to them, exaggerate to themselves the signs of a return to health Nevertheless, with a collection of cases such as Dr Williams gives us in his pamphlet, it becomes the duty of responsible physicians throughout the country to investigate the subject thoroughly in a spirit of perfect fairness and without prejudice, and to let the future decide whether others meet with equally successful results

It has been my desire since seeing Dr Williams's cabinet to find if any similar method of practice has been used before, and my attention was called to a cabinet used by a practitioner not of the regular profession in this city In a pamphlet issued by him, a woodcut of his cabinet was shown which seemed to resemble almost precisely in principle that of Dr Williams, and the description of its use as expressed in the pamphlet led me at first to believe that they were identical, with the exception that no attempt was made to use a spray in connection with the cabinet I visited the gentleman and was received with courtesy, and the principles of the cabinet were explained to me The description of the apparatus in the pamphlet speaks of the air being partly exhausted about the patient at his will Upon questioning the gentleman more closely, however, I found that the breathing tube and stop cock on the inside of the cabinet were not used at all in the same manner as in Dr Williams's apparatus, and I cannot do better than quote the gentleman's words as nearly as possible "I exhaust the air in the cabinet to an amount causing a pressure on the outside of the cabinet of of about three to five pounds to the square inch (an equivalent of a depression of six to ten inches of the mercury), and direct the patient if he become nervous to open the stop cock *very slightly*, so that the outside air may enter enough to reassure him, and then let him sit in the rarefied air for a certain length of time, and at the end of the sitting make him take one or two deep inspirations to expand his lungs, opening the stop-cock a little at the same time, the end being in the mouth" From this description it will be seen that his method resembles more those previously spoken of, in which the patient merely sits in a rarefied atmosphere for a given time No attempt is made to breathe in and out, as in Dr Williams's cabinet, indeed, this would be impossible with the great amount of rarefaction used, for the force of air rushing in through the wide open stop-cock would severely injure the patient, moreover, as I said before, no attempt is made to combine the spray with his apparatus So it will be seen how essentially the two methods differ at the outset, to say nothing of the fact that while in the one case we are dealing with a scientifically educated physician, in the other we come in contact with one who professes to "diagnosticate his case by his eye", who "never auscults nor percusses his patients nowadays," and who "draws the corruption out through the skin," etc, etc

I have endeavored to give the important facts relating to Dr Williams's apparatus, and to show how it differs from other methods of treatment as far as I have been able to learn of them by reading or by personal observation My object will be accomplished if the paper shall excite discussion, and I trust if there is any one present who knows of methods of treatment resembling those of which I have spoken, he will speak of them to the Society this evening

MEDICAL PROGRESS

OBSTETRICS AND GYNÆCOLOGY

Operation for the Cure of Sterility in Cases of Conical Cervix with Flexion of the Cervix —Dr Graily Hewitt, in describing this operation, says One of the rather common causes of sterility in women is the presence of what is termed "conical" cervix This term expresses, however, only imperfectly the real explanation of the difficulty More generally the vaginal portion of the cervix is elongated, as well as conical, and the whole of the cervical canal is also, in the majority of cases, much curved These are the cases *par excellence* which have been termed by Emmet "flexion of the cervix" In such cases, the uterus appears to have gone through a series of changes subsequently to arrival at puberty, namely, (1) imperfect nutrition, (2) softness and want of tone, (3) gradual acquirement of anteflexed shape, mainly as a consequence of the imperfect nutrition and softness of the uterus, and (4) a further and exaggerated condition of flexion of the cervix of the uterus Resting on the floor of the vagina, the vaginal part of the cervix becomes, as it were, doubled up, so that the os uteri looks upwards and forwards The condition of the uterus thus associated with conical cervix constitutes one very difficult to deal with, especially if, as sometimes happens, the uterus, as a whole, be tilted backwards, constituting retroversion, conjoined with extreme anteflexion

Thus, the vaginal cervix is not only too long, but it is sharply curved, and the combination appears to be a great obstacle to conception

Two principal methods have been heretofore recommended, namely, (1) amputation of a portion of the cervix, and (2) opening out the cavity of the cervix by a median incision through its posterior wall, as recommended by Emmet and Sims Another method of treatment would be the use of an intra-uterine stem

A short time since, a patient, with a very decidedly curved and elongated cervix, was sent to me The patient was very anxious to have a family, and suffered much from disturbance of micturition, and difficulty and pain in walking, due to the anteflexed uterus She had been married four years She was treated by means of a cradle pessary, modified to suit the case, with success as regards general comfort, but the sterility remained Last year, I performed an operation on this patient, which I now describe, and which seems to me worthy of further trial in such cases My object was to straighten, as well as shorten, the cervical canal as regards its vaginal portion

Having drawn down the cervix, I removed from its posterior aspect, in the median line, a portion of mucous membrane, nearly an inch in length vertically and half an inch wide, and, having done this, stitched the upper and lower margins together, the effect of the procedure being to shorten the vaginal cervix on its posterior aspect, to draw the os uteri backwards, and thus straighten the vaginal cervix and increase its patency When the stitches, three in number, were tightened, the vaginal cervix was made to look downwards, instead of upwards The sutures were removed after a few days The operation was done at the beginning of the year 1884, and the patient informed me recently that she expected her confinement in the beginning of May

I consider the above a better procedure than amputation of the vaginal portion, because it leaves the os uteri in a natural state, and I think it preferable to Emmet's operation, because it leaves the cervical canal intact The uterus, as a whole, is less mutilated by this procedure, and presumably, its functions may be supposed to be better exercised when the cervical canal and the os uteri externum are preserved It may be remarked that the use of the stem is less likely to be attended with benefit in these particular cases, for the vaginal portion is too long, and something must be done to shorten it, although the use of a stem might be useful, in order to further improve the patency of the cervical canal, after the vaginal portion has been shortened by the procedure above described In the case related, however, the operation alone appeared to produce satisfactory results —*British Medical Journal*, June 13, 1885

SURGERY

EXCISION OF THE RECTUM FOR EPITHELIOMA — DR GEORGE ELDER reports, in the *Medical Chronicle*, for June, 1885, the case of a woman, æt 44 years, with a good record of family and personal health, who for nearly a year before her admission into hospital, Nov 29th, 1884, had been losing flesh and condition, but at first the local symptoms were so slight that they were attributed to a passing attack of piles As time wore on, the bleeding, which had been only slight and occasional, became more profuse, and occurred with every movement of the bowels There were also distressing fits of rectal tenesmus and colicky pains, and the motions, which for months had not been natural in size or form, finally were small, unformed, and forced by the habitual use of purgatives There was a constant oozing of bloody slime, but except at defecation, when pain and straining were severe, there was but little uneasiness On digital examination, about three inches up the bowel, and on its anterior surface a friable, mushroom shaped growth, with a broad attachment, could easily be felt The free mucous membrane above it was beyond the reach of the finger

On Dec 9th, with patient under the influence of ether, a semicircular incision was made around the upper and lateral margins of the anus, and the necessary dissection completed, partly by the knife but mainly by scissors Only two arteries required ligation To expedite matters, after the bowel had been partially freed it was cut away, so that traction could be the more easily applied, by means of vulsellum forceps, to the remaining portion When sufficient had been separated an ecraseur wire was applied well beyond the growth, and this completed the operation In all, rather more than three inches of the anterior two-thirds of bowel were removed On Jan 10th the wound had fairly healed, and a good sized formed motion was passed, causing her pain if she strained On Feb 6th the patient said she had perfect continence of fæces, and passed daily, without the use of aperients, a formed motion

Microscopic examination of the growth showed it to be a cylindrical-celled epithelioma

LOCALIZATION OF THE ANO-VESICAL CENTRE — KIRCHHOFF *(Archiv fur Psychiatrie und Nervenkrankheiten*, Band XV, p 607, 1885), describes a case of fracture of the first lumbar vertebræ in a man, aged 30 years, who had fallen from a horse on the nates Immediately after the accident the patient was paralyzed in the lower extremities, and had to keep his bed for a quarter of a year During this time he suffered from pains in the legs and vertebral column, while the urine had to be withdrawn for the first three weeks by the catheter, but afterwards there was incontinence, and the urine, which was at first clear, became turbid and fœtid In addition, there was an involuntary discharge of fæces The condition of the patient improved under treatment, and he was again able to walk, but the paralysis of the sphincters remained The accompanying cystitis was also improved by treatment, but it always recurred, and ultimately it became complicated by a pyelo nephritis with the usual elevation of temperature, and the patient died nineteen months after the accident At the autopsy, the portion of the vertebral column consisting of the eleventh and twelfth dorsal and first three lumbar vertebræ was removed and sawn longitudinally It was then seen that the first lumbar vertebra was compressed into the form of a wedge, with the point directed forwards, while the base, which scarcely measured two cm in vertical extent, was directed backwards, and displaced so that it encroached to the extent of one cm upon the vertebral canal The whole of the spinal cord in the portion of the vertebral column removed was small and atrophied, while opposite the first lumbar vertebræ it was flattened and pushed to one side The atrophy had reached its highest degree at the conus medullaris, especially on the right side and on a level with the origin of the second, third and fourth sacral nerves

Transverse sections at these levels showed that on the right half of the cord the white columns were much atrophied, and that the ganglion cells had disappeared from the anterior cornu The nerve roots themselves were intact The author argues from this case that the ano-vesical centre is situated on a level with the third and fourth sacral nerves, the portion of the cord which was the chief seat of the lesion, a locality which almost corresponds with the sacral nuclei of Stilling —*Medical Chronicle*, June, 1885

EXCISION OF BOTH BREASTS AT THE SAME TIME — MR JONATHAN HUTCHINSON closes a paper on this subject as follows If it be asked whether, in cases of double disease, it is better to remove the two breasts by a single or by separate operations, I would venture, without hesitation, to recommend a single one, as probably involving both less risk and less inconvenience to the patient —*Brit Med Jour*, June 13

SATURDAY, AUGUST 1, 1885

THE INTERNATIONAL MEDICAL CONGRESS AND ITS ENEMIES

The further the few members of the profession, in three or four cities, who made the mistake of supposing they constituted the embodiment of the medical profession in the United States go, in trying to justify their deliberate attempt to obstruct the necessary preparations for a proper organization of the Congress, the more they involve themselves in gross inconsistencies and misrepresentations Under the head of "Why the New Organization of the Congress should be repudiated," the Editor of the *Medical News* attempts to give the reasons why the action of the Committee of Arrangements at its meeting in Chicago should be rejected

The editorial mentioned (see the *Medical News*, July 25, 1885, p 96) contains five paragraphs, each of which contains one or more misrepresentations of fact, although the *reasons* given are only two, and are stated in the first paragraph as consisting in part of a "disapproval of the rules adopted by its managers, and in part of the fact that these managers are not men who should be endorsed to the world as the leaders of the medical profession of the United States" It is worthy of note, that these two are the *only reasons* that have been given in any quarter for all the bluster and bravado of opposition thus far exhibited And it would be a sufficient answer to both, to say, as we have said substantially before, that there is *no* "New Organization" of the Congress in existence Before the work done by the Committee of Arrangements in Chicago could be completed or made ready for publication, the preconcerted game of bluff was commenced, and a most industrious effort made to propagate the *strike* throughout the country Yet after the lapse of a full month the whole number of those whose names have been announced as having refused to accept any position in the Congress under what they are pleased to call the "New Organization," is only about ninety, of the nearly five hundred embraced in the proposed organization, and certainly only an infinitesmal fraction of the 40,000 members of the profession embraced in the American Medical Association and the several State and local societies in affiliation with it

By "managers" the objectors must mean the members of the Committee of Arrangements consisting of one from each State, and selected by the delegation of each State present at the meeting in New Orleans This body of representative men, selected *not by the presiding officer of the Association, nor by* a committee that might possibly have been packed for the purpose, but by the representatives from each State acting by themselves and for the profession of their State, are sneeringly spoken of as "not men who should be endorsed," etc It is well known that nearly all this sneering is really aimed at the member of the Committee representing the State of Pennsylvania, though the *News* has not the manliness to say so But Pennsylvania was represented at the meeting of the Association in New Orleans by thirty two delegates and permanent members, who alone are responsible for the selection of the proper man to represent the State on the Committee of Arrangements In selecting Dr John V Shoemaker they certainly secured an active, industrious, and efficient representative on the Committee He had done good service as Chairman of the Section of Practice of Medicine, Materia Medica and Physiology at the meeting of the Association in Washington the year previous, and we suspect that the head and front of his offending consists in the fact that he has had sufficient courage, industry, and talent to push his way to position and influence in the profession without going through the hereditary ruts and mutual admiration circles, for which a part of the profession in the quaker city is noted

Again says the editorial in the *Medical News* "It is true that the New Orleans meeting by no means represented the Association, and was *specially packed* with delegates from two or three neighboring States, whose chief purpose in being present appeared to be to obtain control of the Congress," etc It is a pity that the writer of that sentence had not examined a few figures before he ventured to record so manifest a misrepresentation At the meeting in New Orleans there were present representatives from thirty-four

States, two Territories, the Medical Corps of the Army, Navy, and Marine Hospital Service The only States not represented were Connecticut, Delaware, New Mexico, and Oregon The whole number of members present was 635 The five States most contiguous to the place of meeting, and from which the Association is represented as having been *specially packed* with delegates, are Texas, Arkansas, Louisiana, Mississippi and Alabama, the first had 69 members present, the second 36, the third 49, the fourth 16, and the fifth 13, making an aggregate membership present of 183, to outvote a total of 635 They aggregated, indeed, twelve less than the five States of Pennsylvania with its 32 members present, Ohio with 37, Indiana 37, Illinois 55, and Iowa 34, making an aggregate of 195 The truth is, there has never been a meeting of the Association held, at which there was not a greater relative proportion of the membership present from the States contiguous to the place of meeting than in New Orleans At that meeting the largest number of members present from any one State contiguous to the place of meeting was 69 from Texas, which was only about one-tenth of the whole number present, while at the preceding meeting in Washington in 1884, Pennsylvania alone had 213 members present, or more than one-sixth of the number, and at the meeting in Cleveland, Ohio, in 1883, the numbers present from the two most contiguous States, Ohio and Pennsylvania, numbered 302, or nearly one third of the whole number in attendance In the light of these statistical facts, the pretense that the meeting in New Orleans either did not represent the Association, or was "specially packed with delegates from two or three neighboring States," becomes too absurd to be entertained by any intelligent member of the profession

But the editorial writer in the *News* reaches the climax of his recklessness and folly when he adds, in the same paragraph from which we have quoted, that the action of the Association at New Orleans was "the work of a comparatively small faction intensely desirous of office" When it is remembered that among the most prominent acts of the first Committee on the Organization of the Congress, in whose behalf the *News* is so clamorous, was the parcelling out of the chief offices of the Congress to themselves until not one of their number was left without an official position in the Congress, and some of them had three or four such positions, while the new Committee, composed of men whom the *News* calls a faction "intensely desirous of office," have appointed not one of their number to a general office in the Congress, but have with a just sense of propriety limited themselves strictly to the work of a Committee of Arrangements, the reckless and desperate straits of those selfish leaders who are vainly endeavoring to maintain the little game of bluff by which they hoped to successfully obstruct the proper preparation for the Congress, become painfully apparent to the most superficial observer

Before going further in this work of misrepresentation and purely factious opposition, we commend to their careful study the letter on a subsequent page of this number of the JOURNAL, headed "Data for the History of the Ninth International Medical Congress," which is from the pen of one of the most eminent and most widely known members of the profession in America As therein stated, the Ninth International Medical Congress will be held according to apppointment The Association by which it was invited will see that it is officered in all its departments by as eminent and honorable men as exist in the medical profession of our country And if the obstructionists desire to have any part in the good work, they will lose no time in converting their opposition into an honest cooperation in enabling the Committee of Arrangements at its special meeting, on the third of September, to complete its work of organization in a satisfactory manner

THE FRENCH COMMISSION AND DR FERRAN

In the editorial columns of the JOURNAL of July 25, we spoke of the almost necessarily futile results of vaccination against cholera, and in the miscellaneous department of the same issue of the JOURNAL we gave an abstract of a letter from an American physician to the *Chicago Tribune* *Le Progres Medicale*, of July 11, contains an abstract of the report of MM Brouardel, Charrin and Albarran, the Commission sent by the Académie de Médicine to Spain to investigate the alleged discoveries of Dr Ferran This report is of two fold interest, as showing the depth to which a member of an honored and honorable profession can sink himself in charlatanry and quackery of the worst form, and also as pointing a moral for those who have entered, and those who propose entering, the fields of scientific research

We cannot give so much space to this article as does the paper from which we take the following summary This Dr Ferran absolutely refused to give any information as to his methods, or to give a specimen of his culture fluid to the Commission, to allow them to work in his "laboratory," or to allow them to see him work The room which he dignified with the name "laboratory" contained, besides an engineer, a "lawyer" and an accoucheur, two micro scopes, neither of which were of greater power than seven or eight hundred diameters (and for all practical purposes in studying micro biology one might almost as well use a pocket-lens), a very primitive stove, without a regulator, no materials for coloring or staining, for which it seems this unblushing quack has no need, some gas burners, and a few quarts of bouillon. Such, says the Commission, was the scientific outfit of Dr. Ferran. This inventory would be alone sufficient to convince any biologist or scientific man that there was something wrong. No one can blame a man for being too poor to buy apparatus—and had Dr. Ferran convinced any scientific man in Europe that he was doing good and honest work, and that he had not the means for obtaining apparatus, we are certain that he would not have been long without them.

Having given some idea of his apparatus, and especially his microscopes, it is obviously unnecessary to quote his assertions regarding the various evolutions of oogones, oospheres, spores, etc. A man with an obedient and hypertrophied imagination, and an inferior microscope, can always see what he wishes to find, and these taken in connection with dishonesty and a desire for notoriety and gain, go far towards supplying a deficiency of apparatus. Dr. Ferran, seemingly to avoid an inquisitive committee, had not preserved preparations or specimens of the comma bacillus in its stages of evolution. The whole report of the French Commission may be summed up in the very significant words: tout ce que nous avons pas voir nous-mêmes n'etait pas nouveau, et tout ce qui etait nouveau nous ne l'avons pas vu. To every appeal and question as to his methods Dr. Ferran replied that his secret was for sale; he wished to be assured of the Bréant prize of 100,000 francs.

It would seem but waste of time for anyone to go to further trouble to investigate this gigantic fraud. If Ferran thirsted for fame, he may be certain that he has attained that kind which is known as notoriety. His example should be a warning for all time to those who would gain reputation or wealth by dishonest work. Of the results of the inoculations it need only be said that the French Commission declares and proves that the statistics are false and wholly unreliable.

A RETROSPECTIVE VIEW OF GENERAL GRANT'S CASE.

The medical history of General Grant's case has not yet been fully reported, but on account of the high position of the patient, the general interest in his case and the publicity given to every movement, we may say, of either the patient or the physicians and the amount of professional and lay criticism, just, unjust and silly, it seems quite proper to give what we may call a *post mortem* opinion of the case.

In some respects there is a certain similarity between this case and that of the late President Garfield, and so far as we remember just now, it is the third case in which public interest in the patient was so great that it was necessary to issue bulletins to the public newspapers, the first case being that of the Prince of Wales, when sick with typhoid fever at Sandringham, some years ago. In the case of the Prince of Wales the diagnosis was exact, but the outcome necessarily uncertain; in the case of President Garfield the exact nature of the injury was not known, and the termination uncertain until the autopsy showed that it could not have been otherwise. In the case of General Grant the diagnosis was exact, and the termination but too certain.

It will be remembered that the eminent surgeons in charge of President Garfield's case were criticized by the public, who knew nothing of the case, and by many medical men who should have known better,—but did not. To say nothing of certain nameless critics in America, so eminent a man and surgeon as Professor Esmarch blundered through several pages only to show how much better it would have been had he said nothing. And within two weeks a kinsman of President Garfield has exhibited a spleen and an amount of silliness which is quite surprising, by asserting that the surgeons and not the bullet killed the late President. In a former editorial we took occasion to speak of the worse than puerile criticisms of certain newspapers concerning the manner in which General Grant's case was being conducted. Those who wrote those criticisms possibly see now how absurd and out-of-place were their ridiculous comments. But more unjust, if possible, than the criticisms of the newspapers, were the unprofessional animadversions of a few medical journals, which stigmatized the bulletins of Gen. Grant's physicians as "advertising dodges." The mere fact of being a consulting or attending physician in that case was a sufficient advertisement, and the bulletins issued were courtesies extended to a sympathetic public.

In conclusion it should be said that there is nothing in the history of the case to show that the physicians were at any time mistaken as to diagnosis or prognosis—nor is there any reason for believing that the treatment should have been different from that which was faithfully and patiently carried out. What might have been the result had the case been taken in hand at an earlier date can only be conjectured, but it is likely that death could, for a time at least, have been averted had the case been treated surgically nine or twelve months ago At any rate, it is a warning against delay in seeking medical advice, especially in cases of tumor, and more especially in cases of tumors of the mouth

"SHOULD PROPRIETARY MEDICINES BE REQUIRED TO GIVE AN ACCOUNT OF CONTENTS?"

Such is the title of a paper read before the *Michigan State Medical Society*, at its late annual meeting, by PROFESSOR ALBERT B PRESCOTT, of Ann Arbor Putting the question in a more proper form, "Should *Manufacturers* of Proprietary Medicines be required to publish the Constituents of these Preparations?" it is one which would probably be answered affirmatively by every physician and every person interested in public health

In some countries, as France, the State acts on the principle that it is the guardian of the adult individual, so far as health is concerned, but in the United States the individual is generally presumed to be capable of judging for himself in these matters—and whether this is more of a presumption or an assumption it is difficult to say Few things are more apparent than the dense ignorance of the masses as to the most common-sense principles of health and treatment of sickness This is apparent even in the higher walks of life, among educated and cultivated people (such as editors of daily newspapers) Professor Prescott very justly says that as the State, in this country, does not assume such charge of the individual as in some other countries there is all the more reason that he should be protected in the matter of buying proprietary medicines should "be protected in the exercise of his greater liberty in the selection of remedies, protected against the mistakes of the careless and against the deceptions of the dishonest If the State so far respects the right of private choice that no medicine requires a legal sanction for sale, so much the more must the State place safeguard against fraudulent imposition upon private choice, and provide favorable opportunity for its more careful exercise In this protection of the individual, it has long been required that a 'poison-label,' with the name of the article liable to act as a poison, shall be placed upon every package of powerful medicine that is dispensed without a physician's record"

At the meeting of the Michigan State Medical Society at which this paper was read, the Committee on State Sanitation was instructed to present "a draft of a bill for a State law requiring proprietary medicines to carry a statement of their *constituents*", and we hope that the Committee will change the letter of their instructions so that the bill will be directed against the manufacturers and not the medicines And to render the law operative, and to prevent fraud, the State Analyst should be instructed to make analyses of all proprietary medicines, bought in open market, at such times as he may think proper or the Board of Health may direct Furthermore, the bill should provide that the names given to the constituents of the proprietary articles shall be such as may be found in dispensatories or pharmacopœias

Just how much good such a law would do it is impossible to estimate There can scarcely be a doubt that, if enforced, it would do some good, it might possibly mitigate the nostrum evil to some extent But what is needed in this country is a law forbidding the manufacture or sale of any proprietary medicine until a competent body of medical men (such as the National Board of Health, or a Committee from the Army or Navy Medical Department) has subjected it to chemical analysis and therapeutic trial, forbidding the advertisement of it as a cure or specific for other affections or diseases than those specified by the acting body, and requiring that the formula be published on each bottle or package

SOCIETY PROCEEDINGS

THE AMERICAN OPHTHALMOLOGICAL SOCIETY

21st Annual Session, held at the Pequot House, New London, Conn, July 15 and 16, 1885

THE PRESIDENT, WILLIAM F NORRIS, M D, OF PHILADELPHIA, IN THE CHAIR

WEDNESDAY, JULY 15, FIRST DAY

DR C R AGNEW, OF NEW YORK, read a paper entitled

OPERATION FOR REMOVAL OF DISLOCATED CRYSTALINE LENS

The patient had been blind as long as he could recollect The iris was tremulous, the lens was opaque and very movable The eye had been painful for some time and recently the other eye had also attracted attention The vision in this eye was $^{0}/_{1}$

The operation for the removal was as follows The patient was etherized and cocaine was applied The eye was secured with fixation forceps An instrument resembling a two pronged fork, termed a *bident* was introduced into the vitreous chamber behind the dislocated lens, pressing it forward The bident transfixed the eye and held the lens in posi tion Section was then made in the ordinary manner and the lens removed The eye was dressed with absorbent cotton and a black silk bandage Antiseptic solutions were used and a four-per cent solution of cocaine was applied twice a day The eye recovered without any unpleasant symptoms The ophthalmoscope revealed atrophy of the choroid and retina The speaker did not claim that all dislocated lenses should be removed, but this instrument facilitated the operation when it was required

Dr David Webster, of New York, reported an

EXTRACTION OF A DISLOCATED LENS BY DR C R AGNEW'S BIDENT

The patient received a blow on the right eye This was immediately followed by loss of sight Examination showed that the lens was dislocated No treatment was recommended at that time Some months later, pain suddenly appeared in the injured eye The lens was found to be cataractous and incarcerated in the pupil Cocaine was applied but did not relieve the pain Atropia relieved the pain Later the lens became loose and was found in the vitreous The tension was normal It was decided to remove the lens The bident was passed back of the lens, pressing it forwards The incision in the cornea was then made and the lens removed with a spoon The eye was dressed with absorbent cotton and recovered without complication V= $^{0}/_{100}$ with 4 5s With the bident many eyes may be saved if the lens can be brought in sight There is no danger from injury of the ciliary body

Dr H Knapp thought that in these cases there was not much difficulty in removing the lens, which could often be accomplished with the loss of very little vitreous, but the danger came in afterwards from inflammatory complications and there the sight was lost He thought it better to at once enucleate the eye and thus lessen the dangers of inflammation He considered the bident, which was exhibited, to be an ingenious instrument For the past six or eight years he had not introduced an instrument within the globe to facilitate the removal of the lens This he was able to accomplish by external manipulation

Dr E Williams, of Cincinnati, considered the instrument an ingenious and useful one, but in most cases he agreed with Dr Knapp that in most cases enucleation was the best procedure

Dr C R Agnew thought that the bident might be useful in the removal of foreign bodies from the interior of the eye He did not acquiesce in the view that enucleation was a simple operation He regarded it as a serious mutilation

Dr C H Williams, of Boston, thought that there was another alternative than those mentioned, and that was the removal of the contents of the eye and closure of the anterior opening with sutures It gives a better stump for the artificial eye

Dr D B St John Roosa, of New York, reported a case of

EXTRACTION OF THE LENS IN ITS CAPSULE

For the past three years the doctor had been in the habit of removing the lens in its capule In a large proportion of cases without iridectomy The use of cocaine has facilitated the operation He referred particularly to the method of dislocating the lens The section is made as usual, but large After puncture and counter-puncture are made, the knife is turned on its back so that it rests on the iris The knife is then moved up and down two or three times until the lens is seen to move, then the section is completed and then the lens can usually be removed with no loss of vitreous The manipulations on the cornea are made with one or two spoons Sometimes after the operation it is rolled under but in many cases the pupil is circular The writer had performed the operation between thirty and forty times, and is satisfied with its success If the lens is not dislocated, iridectomy may be performed and the operation practiced A paper on the subject is to be found in the Transactions of the New York State Society, and in the *Medical Record* for February 1885

Dr J A Andrews, of New York, read a paper on

THE TREATMENT OF PURULENT CONJUNCTIVITIS

The treatment is based upon the belief that the contagious element is of the micrococcus variety He related a case in which he had secured an inoculation of the seventh generation of a pure culture of a gonococcus This is the first case inoculated with the gonococcus He showed an instrument which he had devised to wash out the conjunctival cul de sac It consisted of an eye speculum with hollow arms through which fluid may be passed He had found bichloride of mercury solution (1 to 10,000) serviceable, but apt to irritate A six per-cent solution of carbolic acid is useful as it inhibits the movements of the white corpuscles Irrigation should be maintained for ten minutes, in order to remove all secretion Nitrate of silver solution (1 to 12 per cent) is then used, and an antiseptic dressing is next applied This consists of vaseline and boracic acid or carbolic acid, but he laid especial stress upon the importance of maintaining irrigation of the conjunctiva by means of the instrument referred to above

Dr Charles S Bull, of New York, reported a case of

ABSCESS OF BOTH FRONTAL SINUSUS

The patient had been hit on the forehead fourteen years previously with a piece of wood This produced a fracture of both nasal bones and deviation of the septum In seven weeks the wound had closed Ten years after the accident a swelling was noted on the upper inner angle of the right orbit, which could be made to disappear by pressure There was complete ptosis An incision was made into the swelling just beneath the orbital margin and a large quantity of pus escaped (two or three ounces) The cavity was washed with a five per-cent solution of carbolic acid No connection with the superior nasal meatus could be detected, but the bony septum between the two frontal sinuses was absorbed, and both sinuses were converted into large cavities The entire ethmoid bone was an immense cavity, the bony suture being absorbed A number of osteophytes were removed A drainage tube was introduced The patient was discharged six weeks after the operation, and recovered completely The ptosis disappeared, and the eye was restored to the normal plane

Dr Knapp recommended the substitution of a silver tube for the rubber drainage tube usually employed

Dr B E Fryer, of Kansas City, reported a case

OF BONY TUMOR OF THE ORBIT

The patient, a boy six years of age, came under observation April, 1885 There was swelling of left orbit which included the whole line of the superciliary ridge It was quite hard Some time before the boy had been struck by a piece of wood, but it was thought that no splinter had lodged beneath the skin It was decided to remove the tumor This was done, and on examination it proved to be a bony cyst, within which was a small piece of wood This was enclosed in bone on all sides The edges of the wound were brought together, and healing resulted without complication

Dr Norris, of Philadelphia, presented a new sheet of

METRIC TEST LETTERS,

devised by Dr Charles A Oliver, of Philadelphia

Dr E E Holt, of Portland, Maine, reported

SOME OF THE RESULTS OBTAINED IN THE COMPILATION OF 1,000 CASES OF REFRACTION

The writer had been in the habit of recording all the measurements connected with the prescribing of glasses As a result he had found in 1,000 cases thus recorded, the average distance between the centres of the pupils of the human eye to be about 60 M M The average of other measurements were given and the importance of the physician determining and designating them, and then seeing that they were carried, was dwelt upon

Dr George C Harlan of Philadelphia, reported a case of

RAPIDLY PROGRESSING MYOPIA CHECKED BY SECTION OF THE EXTERNAL RECTUS

The case was that of a boy of 16, in whom myopia was progressing rapidly The external rectus was divided seven years ago The internal rectus was also exercised by the use of prisms Since then then there has been no increase of the myopia

Dr Samuel Theobald, of Baltimore, reported

THREE CASES OF PROGRESSIVE ASTIGMATISM

Astigmatism of traumatic origin, he remarks, is observed not infrequently to undergo changes in degree, but it has been commonly held that congenital astigmatism does not alter in degree, though the refraction of the eye as a whole may undergo marked change The cases which he reported, he thought, proved that there were some exceptions *to this rule* The first case was that of a young man who, with a high grade of hypermetropia, had astigmatism of each eye which required for correction, A plus $^1/_{60}$ C The case was observed at intervals during a period of twelve years, and during that time the astigmatism increased until finally A plus $^1/_{13}$ C was needed to correct it

The second case was one of compound myopic astigmatism in a young man, in which there occurred, along with an increase of the myopia, a growth of the astigmatism, during a period of 16 years, from $^1/_{16}$ to $^1/_{8}$

In the third case a simple myopic astigmatism, in a physician 25 years, requiring A $^1/_{4}$ C in one eye and A $^1/_{30}$ C in the other for its correction, changed in five years so that A $^1/_{11}$ C and A $^1/_{13}$ C respectively, were needed

The speaker *regretted that the examinations* had not all been conducted under a mydriatic, as they would then be more apt to carry conviction to the minds of those disposed to be sceptical regarding the progression of astigmatism He did not believe that the result would have been *different Such cases* are not frequent, but it is important that the fact should be recognized As the increase of astigmatism is probably due to change in the corneal curvature, the phenomenon should be met with more frequently in the yielding myopic, than in the relatively stable hypermetropic eye

AFTERNOON SESSION

Dr Lucien Howe, of Buffalo, exhibited an arrangement for the demonstration of refraction and accommodation It consists of two bands of thin metals bent in such a manner as to represent the outlines of a double convex lens, and passing through it two jointed rods representing the rays of light ordinarily figured as passing through such a lens, and joining at its focus The flexible bands were attached to each other above and below, so that by approaching or separating the sides, they could be made to show less or greater convexity The rods representing the rays of light were jointed near the centre in such a way that while the two halves could be placed in such a direction as to show the light as entering parallel to the axis of the lens the other two portions could be bent to a point to show the convergence of rays at the focus By alteration in the position of these rods, and also in the forms of the bands representing the lens, all the different variations of the laws of refraction and the changes in accommodation can be demonstrated to a class

Dr C S Bull reported

TWO CASES OF UNILATERAL TEMPORAL HEMIANOPIA

The first case was that of a man aged 60, first seen in 1884 In 1849 he received an injury which rendered him unconscious When he regained consciousness he found that he was blind in the right eye *In 1883 he noticed a central obscuration of* vision in the left eye There was no syphilis, no disease of the heart, and no indication of Bright's disease He had never used alcohol to excess, but smoked and chewed tobacco in large amounts There was an irregular central scotoma The media were transparent and the iris normal Both optic discs were of a dirty white color, and in both there was a deep excavation with pulsating veins, and in the left eye there was a retinal hæmorrhage The tension was normal

The second case occurred in a man aged 60. He had been knocked down by a horse, receiving a depressed fracture of the frontal bone above the left eye. The patient was unconscious or delirious for four weeks following the accident. When he regained consciousness, he found that the left eye was blind. Examination showed that in the left eye there was somewhat irregular temporal hemianopsia. This may have resulted from fracture of the superior orbital plate, with injury to the fibres of the optic nerve going to the temporal half of the retina.

Dr. Haskett Derby, of Boston, reported

TWO CASES OF PENETRATION OF THE EYE BALL BY SCISSORS IN THE OPERATION OF STRABISMUS.

The first case was that of a young man on whom an operation for strabismus had been attempted. The surgeon inadvertently picked up a pair of sharp pointed scissors. The point of the scissors suddenly penetrated the eye ball and a portion of vitreous as large as a cherry stone escaped. The operation was abandoned and Dr. Derby was called to see the case. The eye was bandaged and the patient put to bed. Several attacks of inflammation supervened, but the patient was discharged on the 41st day with $V = {}^{1}/_{10}$.

In the second case the scissors also entered the sclerotic, but after a somewhat tedious convalescence the wound was found closed on the 21st day with vision as good as before the operation.

Dr. Knapp stated that he had done 3,000 squint operations, and in three cases he had punctured the sclerotic. He, however, completed the division of the muscle and the patients recovered as readily as from an uncomplicated operation.

Dr. Mittendorf had been present at a strabismus operation where the sclera was opened. He advised the surgeon to complete the operation. This was done and the wound had healed in four or five days. He thought that in case the accident happened that the division of the muscle should be completed.

Dr. E. Williams reported a case in which he had punctured the eye. The patient recovered without difficulty.

Dr. E. E. Holt read a paper on

STRABISMUS, ITS CORRECTION WHEN EXCESSIVE, AND IN HIGH DEGREES OF AMBLYOPIA.

The writer had employed advancement of the weakened attenuated muscle in connection with tenotomy, in certain cases of squint, and after tenotomy alone had failed to correct the deviation. He also exhibited an apparatus he had devised for showing the associated and accommodative movements of the eyes and the effects of tenotomy and advancement of the muscle in correcting squint.

Dr. C. J. Kipp at one time employed advancement, but he had given it up because it was difficult to graduate the result.

Dr. W. W. Seely, of Cincinnati, read a paper on

THE TREATMENT OF STRABISMUS INTERNUS.

He said that each year, with its added experience, had strengthened the conviction that early operations (up to the tenth or fifteenth year) are questionable, and possibly should be entirely abandoned. He combatted the idea that crossed eyes never become straight without an operation. Nothing is better established than the relation between ametropia and strabismus, and all recognize the necessity for glasses to prevent the recurrence of squint after tenotomy. Every one knows that it is possible to correct the squint by setting aside the ametropia by means of glasses. My early conviction that something should be left to time and glasses has long since grown into an absolute law of action, for I have become thoroughly persuaded that immediate perfection meant later in life, insufficiency, or even divergence. Operative procedures should not be the first consideration, but should be looked on as an adjuvant to be resorted to later on, if necessary.

He summed up as follows:

1. That with our present light, routine operative interference is wrong.
2. That to thoroughly correct the deviation in young children by operative interference is extremely liable to subject them in after life to insufficiency or external squint.
3. That a later period of life, if anything, favors better results from operative interference.

Dr. Knapp thought advancement a dangerous operation. He had always been able to correct the deviation by two or three tenotomies, and if necessary, stitching the eye to the commissure.

Dr. Theobald endorsed Dr. Knapp's views in reference to advancement. He was surprised at the conclusions of Dr. Seely. Squint operations in his hands had been very satisfactory. If postponed they are likely to prove unsatisfactory on account of the amblyopia which is liable to develop.

Dr. O. F. Wadsworth, of Boston, had studied the subject for a long time and had convinced himself that amblyopia from squint did not occur. The ability of the patient to use the vision which he has does seem to be lost by a continuance of the squint, but it may be recovered by practice. If the examination of vision was carefully made, he was certain that it would be found that the vision was not improved after the operation. It, however, is often difficult to get the full amount of vision which a squinting eye possesses.

Dr. R. H. Derby, of New York, reported a case of

ECTROPION OF BOTH LIDS, BLEPHAROPLASTY BY THE ITALIAN METHOD.

The displacement of the lids was the result of cicatricial tissue from a severe and extensive burn of the face. The lids were loosened from their attachments and the new lids formed from flaps raised from the arm. The arm was bound to the head with water glass plaster, and the pedicle was not divided until union had taken place. Photographs were exhibited showing the appearance of the patient before and after the operation.

Dr. Haskett Derby exhibited a box of

TRIAL LENSES,

made by Nachet, in which the following features were embodied:

1. The doubling of the prisms.

2 The distinguishing of the cylindrical lenses by coloring the positive settings black and the negative red

3 The adaptation of the trial frames to receive the glasses without removal from the patient's head

4 The removal of the handles from the prisms and cylindrics

Dr B Joy Jeffries, of Boston, read a paper entitled

PLASTIC OPERATIONS WITHOUT PEDICLES

The object of the paper was to make one or two suggestions which the author had not yet put in practice, but which he was ready to try when opportunity offered He suggested the use of the prepuce from the circumcision of Jewish children for operations about the eyes He also suggested that in plastic operations the desired result might be obtained without the use of a flap by employing carbolized oil dressings to retard healing, for it is well known that some time after a plastic operation the transplanted tissue has almost entirely disappeared

(*To be continued*)

DOMESTIC CORRESPONDENCE

DATA FOR THE HISTORY OF THE NINTH INTERNATIONAL MEDICAL CONGRESS

Sir —It is sometimes a useful aid, in judging of current events, to project the thoughts into the future and consider the light in which the present will appear in history With no other than fraternal sentiments, a personal application of this remark is commended to those who have taken an attitude of opposition to the arrangements for the International Medical Congress which is to hold its ninth session in America in 1887 The history of this Congress will be written This Congress will be regarded hereafter as one of the most important of the events embraced in the annals of American medicine All the circumstances connected with it will be on record In this article will be noted, for the benefit of the future historian, facts which have occurred up to the present date Where could they be more properly chronicled than in the columns of the Journal of the American Medical Association?

The American Medical Association, at its stated annual meeting in May, 1884, resolved to invite the Congress which was to meet in Copenhagen in August, to select the United States as the place of meeting for the next Congress This was resolved unanimously without discussion A Committee of eight was appointed to tender the invitation The invitation was tendered and accepted If we are correctly informed, there was no considerable reluctance manifested in the acceptance of the invitation Some objections were made on the score of the difficulty of attendance on account of the distance and the expense, but, in fact, no other invitation was before the Congress Some German members desired the next meeting to be held in Berlin, but no one was authorized to tender an invitation The same was true of Italy Here it is to be remarked that in our country there is no existing organized body competent to invite the Congress in behalf of the profession of the United States, except the American Medical Association Whether it be true or not that this Association represents fairly the profession of the whole country, no other organization has any claim whatever to such a representation An invitation could come from no other source, unless a convention were to be called for that express purpose

The functions of the Committee appointed by the American Medical Association did not end with the tender of the invitation The Committee was authorized to enlarge its membership without limitation and to form a permanent organization Moreover, it was considered that the resolutions under which the Committee was appointed, empowered it to nominate the officers of the Congress and to make all other arrangements for the meeting without need of any further action on the part of the Association The Committee, in short, believed that the entire management of the Congress had been committed to it by the Association, and it proceeded to do the work which, according to this belief, devolved upon it The result of this work is contained in the publication entitled, "International Medical Congress, Ninth Session, to be held in Washington, D C, in 1887 Rules and preliminary organization" This publication, issued under the sanction of the Committee, was distributed in this country and in other countries It was not to have been expected that the work of the Committee would be satisfactory to all Many must have felt that they were overlooked The distribution of the nominated officers of the Congress could hardly fail to provoke criticism It was hardly possible that errors should not be committed At the meeting of the American Medical Association, at New Orleans, in April, 1885, the report of the Committee called forth objections in two points of view One of these related to the geographical distribution of the officers nominated by the Committee It was objected that certain portions of our vast country were not sufficiently represented This was certainly not an unnatural objection, for it is needless to say that there exists a certain amount of sectional patriotism or pride, or jealousy, whichever of the terms we choose to apply to it, demanding recognition in all national affairs

Another objection had reference almost exclusively to one State of the Union—the State of New York In this State, for the past few years, a portion of the medical profession have revolted from the American Medical Association, and repudiated the Code of Ethics, the acknowledgment of which is a condition of membership of the Association One half of the officers nominated for the Congress from the State of New York, were taken from that portion of the profession This objection was more particularly dwelt upon These objections gave rise to a heated debate at the meeting of the Association In this debate warmth of language was used by some, as is generally the case in heated debates, and for this individuals, and not the Association, are to be held responsible As a result, the Association provided for the appointment of a new Committee consisting of members representing all the States of the Union and the Territories, with instructions to revise the work of former Committee. The motives of those who raised the objections have been questioned. It is asserted that the objections were raised in consequence of the supposed claims of the objectors not having been duly considered in the organization of the Congress. We shall not stop to discuss this question, as we are here dealing with facts, not motives. Suffice it to say, the Association recognized by a good majority the validity of the objections, whatever may have been the motives of those who were prominent in bringing them forward.

Whether or not it was wise to disturb the proceedings of the first Committee, even assuming the validity of the objections to them, is a question which is certainly open for discussion. There can, however, be no question as to the competency of the Association to do what was done. The invitation was given, it is true, in behalf of the medical profession of the United States. But it was given by the American Medical Association as representing the profession of the United States. The Association assumed responsibility for it. The Association thereby is entitled to credit if the Congress prove successful, and would be liable to censure were the Congress not successful. However unwise the action of the Association may have been, there is no appeal except to the Association itself. In dealing here with historical facts, we do not discuss the wisdom of the action of the Association.

The newly appointed Committee held a meeting in Chicago on the 24th and 25th of June, 1885. This Committee, it is to be noted, included the eight members who constituted the original Committee appointed by the American Medical Association. Following the distinctly expressed wishes of the Association, the Committee in Chicago substituted other names for the names of those nominated by the first Committee who had declared themselves as repudiating the ethics of the Association. Other changes were made with a view to geographical representation, and a certain number of new names were added. Membership of the Congress was restricted to delegates from the American Medical Association, and State and local organizations in affiliation therewith. An official publication of the proceedings of this meeting has not yet appeared, and it is understood that the publication will not appear until after another meeting of the Committee, which it is expected will take place within a few weeks. This delay, as is seen by an editorial in a recent number of the JOURNAL, is for a further consideration of new nominations, and a revisal of the rules of the Congress.

We come now to occurrences which to the future readers of the history of the Ninth International Congress will seem truly remarkable. Directly after the meeting of the Committee at Chicago, five of its members, who had been members of the original Committee, sent their resignations to the Secretary. These resignations taking place after the adjournment of the Committee, the vacancies could not be promptly filled, and the effect, whether so intended or not, was to cripple the Committee in obtaining a quorum for a subsequent meeting. Simultaneously, or nearly so, with this action, several members of the medical profession in Philadelphia, who had been nominated for official positions, held a meeting and agreed to decline any connection with the Congress under the existing organization. An announcement of this agreement was published without delay in the medical journals of New York as well as Philadelphia. Similar meetings took place in rapid succession in Washington, Boston, and Baltimore, at which similar resolutions were adopted and immediately furnished for publication. The resolutions adopted in these several cities are essentially the same, differing only in phraseology. They do not contain any explicit statement of complaints or grievances. From other sources it appears that dissatisfaction with the persons who compose the present Committee, and especially with the Secretary and Chairman, enters largely into the reasons for declining to accept any position in the Congress. The writer is not prepared to discuss this ground of opposition, were it decorous to do so. It must be said, however, of the Committee, that it apparently sought only to carry out the views of the American Medical Association, and has not nominated its members to important positions in the Congress. Moreover, the functions of the Committee in a great measure end when the organization of the Congress is completed. The work which then remains to be done, devolves chiefly on the Secretary General and other officers nominated by the Committee. It cannot, therefore, be said that the officers and other members of the Committee have taken any advantage of the opportunity to secure for themselves official positions. Their ambition seems not to have extended beyond the privilege of placing others in these positions, and the exercise of this privilege imposes upon most of them considerable inconvenience and expense. An objection to the Committee has been raised on the ground that it designs to restrict improperly the conditions for membership of the Congress. As the proceedings of the Committee have not been published, and moreover, their action in regard to the rules of the Congress is not yet completed, this objection is, to say the least, premature. The American Medical Association enjoined upon the Committee the duty of not nominating as officers of the Congress those who have repudiated the ethics of the Association. This restriction does not extend to membership of the Congress. From all that is at present known of the views of the Committee, it may be inferred that there will be no restrictions, as regards membership, on members of the regular profession. This is in accordance with the custom hitherto at the meetings of the International Medical Congress.

There seems to be no valid reason for complaint on the part of those who have made haste to announce their antagonism to the Congress, unless the elimination from official position of those who have disqualified themselves from membership of the American Medical Association be so considered. How many of those who have united to oppose the Congress are willing to admit this as the reason of their action? Practically, however, their action sanctions and encourages those who have attempted to break down the barrier between the regular profession and those who ostensibly practice homœopathy or other exclusive systems of medicine, and it virtually rebukes those who have so earnestly and successfully labored for the honor of the medical profession by sustaining the National Code of Ethics. Have all those who decline connection with the Congress under its present organization, reflected upon their action in these points of view? They cannot have given the matter due consideration. Nothing disrespectful is intended in saying that they have acted with undue haste. How often, under a temporary excitement based on misapprehensions, are conclusions formed and measures taken, which are reconsidered and relinquished after a little sober reflection!

A similar action, in quick succession, in several cities, of members of the medical profession, shows undoubtedly a concerted movement. Now concerted movements are for certain definite objects. What are the objects in the present instance? It is not to be supposed that they who have joined in this movement have done so purely from a desire to bring discredit on the profession of the United States by placing obstacles in the way of the success of the Congress. We will not venture to surmise the objects, but leave them for the future historian of the Congress. Whatever they may be, there are certain considerations which, with reference to the movement, it behooves the reflecting members of the medical profession of the United States to bear in mind. One of these is the certainty of the meeting of the International Congress in 1887. At the present moment an International Congress does not exist. The Eighth Congress existed and ceased to exist in August, 1884. The Ninth Congress will exist in America in September, 1887, and meanwhile there is no organization competent to appoint any other time or place for its coming into existence. It is true the American Medical Association at its next meeting might publish to the world that it recalled the invitation to meet in this country in 1887. Does any one suppose that this will be done?

Another consideration relates to the officers of the Congress. The work of the Congress will devolve upon certain of its officers, viz. the President, the Secretary-General, the Chairmen and Secretaries of the different sections, the Finance Committee, the Executive Committee, and the local committee of arrangements. The Vice Presidents, Secretaries, and members of the Council may be said to be ornamental, inasmuch as they are exempt from active responsibility. Now, there is no lack of members of the medical profession in this country competent to do the active work of the Congress. The success of the Congress is not dependent upon a limited number of the members of our profession, however distinguished they may be for professional attainments or however desirable may be their cooperation. There can be no risk of failure from inability to fill worthily the places of responsibility. This is as true of our country as it was of England in 1881. The offices in the English Congress were admirably filled, but who can doubt that hundreds of physicians and surgeons in Great Britain would have filled these offices worthily? The success of the Congress, so far as it depends on the resources of our own country, is to be promoted more by contributions to the subjects belonging to the several sections than by the selection of officers.

It seems to be a notion with some that the attendance on the Congress of foreign members will be greatly affected by the nominations for officers, and that troubles connected with the organization of the Congress will deter many from attending. This idea is too absurd to call for discussion. The organization of the Congress in other countries probably encountered more or less local jealousies and intrigues. What cared we for these? And what will the profession of other countries care for our local difficulties? Our transatlantic brethren, it must be admitted, are more discreet than we are as regards the washing of soiled linen. They are less inclined to give publicity to local or personal bickerings, and it is to be hoped that those connected with the medical press will take no notice of what properly belongs within the limits of domestic privacy.

The Ninth International Medical Congress, it is safe to predict, will be a success whatever may be the obstacles to be overcome. The medical profession of the United States will not be satisfied to have this Congress fail to be successful. But let it be considered that the success will be the more complete, and thereby more gratifying, more creditable, and more useful, the nearer the approach to unanimity in the efforts of the profession of the whole country to make it successful. Who will say that Surgeon J. S. Billings misrepresented the medical profession of the United States when he assured the Congress at Copenhagen that his "countrymen would do their best to secure that the future Congress should effect as much as possible for the advancement and coordination of medical science?"[1]

NECROLOGY

JOHN STAIGE DAVIS, A.M., M.D.

Died, at his residence at the University of Virginia, on July 18, John Staige Davis, Professor of Anatomy and Materia Medica in the University. He was stricken with left hemiplegia and left hemianæsthesia, with some degree of amnesic aphasia, on May 13, and his condition was very critical for about two weeks, when it became more favorable. Subsequently, however, there was a second stroke of paralysis, and death took place on July 18.

John Staige Davis was born in Albemarle Co., Virginia, on October 1, 1824, and was therefore in his sixty-first year at the time of his death. From early childhood he was a close and earnest student, as shown by the fact that he received his degree of Master of Arts at the University of Virginia at the early age of 17 years, and his Medical degree at the same institution one year later, July 4, 1841 From this time until December, 1842, he was a student in one of the hospitals in Philadelphia He then settled in Jefferson Co, Virginia (now West Virginia), whence he removed to Charlottesville, near the University of Virginia, in January, 1845 From 1845 until 1849 he filled the place of Demonstrator of Anatomy in the University, and in 1849 he took the Chair of Anatomy and Materia Medica The amount of work which fell to his care was now enormous, as the medical class of that year numbered 127, and Professor Davis was without a Demonstrator of Anatomy His duties were efficiently and ably performed however, to the satisfaction of both the pupils and the Faculty

---

[1] The Social History of the Eighth International Medical Congress by D. Bryson Delavan, M.D.

As a lecturer and teacher, Dr Davis has had few equals in America Several years ago an eminent physician and professor said of him "I studied anatomy under Dr Davis, and then went abroad, where I sat under the most eminent anatomists of Europe Cruveilhier was the peer of them all, but Dr Davis, as a teacher and lecturer, is easily the peer of Cruveilhier" Nor was his personal popularity exceeded, among his students, by his popularity as a teacher With but very few exceptions, the feelings of his classes towards him were those of respect and love He was a kind and affectionate friend, and his death will be deeply deplored by many personal friends and pupils, and by the friends of the University of Virginia

BOOK REVIEWS

Manual of the Antiseptic Treatment of Wounds for Students and Practitioners By W Watson Cheyne, M B, F R C S, Assistant Surgeon to King's College Hospital, etc 8vo, pp xiii, 151 With illustrations New York J H Vail & Co, 1885

This manual, *the author tells us*, is written with the view of enabling students to obtain a thorough knowledge of the practical details of the best methods of treating wounds The nine chapters treat of Repair and Dangers of Wounds, Bacteria and Disease, Destruction of Bacteria, Aseptic Surgery—Materials Employed, Aseptic Surgery (two chapters), Aseptic Surgery—Modifications, Antiseptic Surgery Before reading this little book we had not thought it possible that so much detailed information could be crowded into so small a space, and without any appearance of crowding, and scarcely of condensation Mr Cheyne has the happy faculty, however, which is by far too uncommon with writers, of knowing when he has come to the end of an argument, Of this book it may be said, as of his other writings, that it is condensed without being abrupt, it is detailed without verbosity, and all the instructions are given with a clearness that is particularly refreshing The oldest and most accomplished surgeon will be repaid for the reading of it, while to the young surgeon it is absolutely indispensable, and even those who do not practise antiseptic methods will learn much from it It is completed by a good index

The Pathology and Treatment of Stricture of the Urethra and Urinary Fistulæ By Sir Henry Thompson, F R C S, M B Lond, etc Fourth Edition 8vo, pp xii, 254 Philadelphia P Blakiston, Son & Co, 1885 Chicago W T Keener

This book is a complete revision of the essay to which the Jacksonian Prize was awarded in 1852, a revision brought up to May, 1885, and with the addition of a chapter on Urinary Abscess, and one on Urinary Fever, and with many additional illustrations It is scarcely necessary to say that the subjects are treated of in detail whatever Sir Henry Thompson writes is worth buying, and should be closely studied

ASSOCIATION ITEMS.

SPECIAL MEETING

Committee of the American Medical Association on International Medical Congress—The Committee appointed in accordance with resolutions passed at New Orleans will meet in special session for the transaction of urgent business, at Murray Hill Hotel, Park avenue and Forty First st, New York City, at 12 o'clock, M, on Thursday, September 3, 1885

The attention of members is called to the following resolution offered by Dr Robert Battey, of Ga, and adopted at the meeting in Chicago

Whereas It is expedient that the meetings of this Committee shall represent, as far as practicable, the profession of all portions of our country,

Resolved, That any member of this Committee who may be unable to attend a meeting shall be empowered to send as his *proxy* for the meeting, any member of the American Medical Association in good professional standing, and a resident of his State, or a member of his Government Department

R Beverly Cole, *Chairman*
Jno S Lynch, *Vice Chairman*
John V Shoemaker, *Secretary*

Philadelphia, Pa, July 24, 1885

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with Five Dollars, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly Journal of the Association will be forwarded for one year

Richard J Dunglison, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

New York State Medical Association—Fifth District Branch —The first *annual* meeting of the Fifth District Branch will be held in Brooklyn, on Tuesday, October 13th, 1885 There will be a morning and afternoon session

All Fellows desiring to contribute to the meeting, either by reading papers, notes or communications, or by exhibiting specimens, are respectfully invited to notify the Secretary, E H Squibb, M D, 36 Doughty Street, Brooklyn, to that effect at their earliest convenience

Deaths from Cholera in Spain —The United States Consul at Barcelona, Spain, makes the following report to the Marine Hospital Bureau of the number of deaths from cholera in the infected districts of Spain from the beginning of its appearance (March 4) to July 4, 1885

Provinces	*Cases*	*Deaths*
Alicante	1,588	646
Castellon	2,617	1,277
Cuenca	78	40
Madrid	1,700	753
Murcia	6,007	2,319
Tarragona	31	19
Fernel	12	5
Toledo	455	207
Valencia	14,928	6,801
Saragossa	628	280
Total	28,044	12,347

[Up to July 18th the deaths were 18,000 to July 25 more than 25,000, and the average of new cases is now over 2 500 daily with 1,000 deaths]

Cremation in Germany —The Berlin correspondent of the *British Medical Journal* says that at the meeting of the Berlin Verein fur Innere Medicin on June 1st, a *petition, drawn up by the Cremation* Society, to be presented to the Reichstag, was laid on the table for signature The object of the petition is to obtain the passing of a law by which cremation may be legal, though not compulsory, in Germany The petition gives various reasons in favor of cremation, the chief one being "that the latest studies of well known authorities in Germany and abroad in the field of hygiene have clearly proved that cremation is the safest preventive against the spread of infectious diseases by corpses" The petition was signed by several of those present at the meeting

Missouri State Board of Health —The following is an abstract from Circular No 1, recently issued by the Board In order that the State Board of Health may receive prompt and effective support and cooperation, and in view of the continually impending menace of a cholera visitation, it is respectfully requested and urged upon citizens of counties and towns that they promptly meet and organize county and town boards of health for their own safety and protection A simple and feasible plan for such an organization in counties where none exist is for the presiding justice of the county court to be made its President, the county clerk Secretary, with three reputable physicians added, one of whom may be officially designated as health officer, and whose powers and duties shall be clearly defined and specified When such an organization is effected it is respectfully requested that prompt notice of the same be sent to this Board

Students of the Berlin University —The number of students matriculated at the Berlin University this term exceeds that hitherto attained in any preceding term In the summer of *1873* there were only 1,590 students in the books, in 1880, the number amounted to 3,365 and this year it has reached 5,465 Comparing the figures in the Faculty of Medicine, we find 340 inscribed in 1873, 924 last year, and this summer 1,072 There are 11 students from Great Britain, and 89 from America

Official Registry of Missouri —The Executive Committee of the Missouri State Board of Health have issued the following

In anticipation of the publication of the Official Registry of Physicians, Surgeons and Midwives of Missouri, which matter was referred to the Executive Committee by the Board—the work to be undertaken so soon as it may be found practical to do so—it is respectfully urged upon all practitioners of medicine etc, who may be entitled to register under the existing law, but who have failed or neglected to do so, to send their names to the Secretary at an early date, in order that the list may be as full and accurate as possible, as well as to secure to themselves the legitimate benefit of publication in the said official registry

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JULY 18 1885 TO JULY 24 1885

Captain Norton Strong, Assistant Surgeon, ordered for temporary field duty with battalion 8th Cav at Hillsboro, N M (S O 34, Hdqrs Dist of N M, June 27, 1885)

Captain F W Elbrey, Assistant Surgeon, sick leave of absence further extended four months on surgeon's certificate of disability (S O 162, A G O, July 17, 1885)

First Lieutenant Edward Everts, Assistant Surgeon, ordered for duty as post surgeon, Ft McDermit, Nev

First Lieutenant A S Polhemus, Assistant Surgeon, ordered for duty as post surgeon, Benicia Barracks, Cal

Captain C K Winne, Assistant Surgeon, ordered for duty at Benicia Arsenal, Cal (S O 68 Dept Cal, July 11, 1885)

First Lieutenant Edward Everts, Assistant Surgeon, ordered for duty as post surgeon, Benicia Bks, Cal

Captain C K Winne, Assistant Surgeon, ordered for duty at Benicia Arsenal, Cal Par 3 S O 70, Dept Cal, July 15, 1885 (Modifies par 2, S O 68 c s, Dept Cal)

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED JULY 25 1885

Fessenden, C S D, Surgeon, leave of absence extended eight days on account of sickness, July 20, 1885

Irwin Fairfax, Passed Assistant Surgeon, granted leave of absence for ten days, July 14, 1885, to inspect unserviceable property at St Louis Mo, July 15, 1885

CARDIOGRAPHY[1]

BY A T KEYT, M D,
OF CINCINNATI OHIO

Cardiography comprehends the art and science of the instrumental registry of the movements and phases of the heart's revolution Or, the term may designate either the art of producing, or the science resulting from, such graphic representations The instrument which writes the changes is properly termed the cardiograph, and the graphic line produced by it, the cardiogram Cardiography is less known and practiced than sphygmography, nevertheless its history is not unworthy of attention

The first successful auto-records of the living heart were obtained in 1860 by Chauveau and Marey in their brilliant series of experiments on the horse These experiments have become classical and their *technique* need not be detailed here Suffice it to state that the variations of the blood pressure in the cavities of the heart and in the aorta, as also the impressions of the heart against the chest-wall were faithfully and simultaneously recorded during the heart's revolutions The results were magnificent, and may be formulated as follows

1 The line of a cardiogram ascends and remains more or less elevated in ventricular systole, while it descends and remains more or less depressed in ventricular diastole, the lowest point of the main ascent marking the beginning of systole, and the highest point of the main descent marking the beginning of diastole

2 The two ventricles are synchronous in their action

3 The auricular systole precedes by a short interval the ventricular systole

4 The trace of the pulsation of the heart taken from the thoracic wall agrees exactly in time and substantially in form with the trace of changes of blood-pressure taken from the interior of the ventricle

5 The ascent of ventricular pressure precedes the ascent of aortic pressure by a short interval, and the ascent of arterial pressure at remoter points, by longer intervals

These precious facts having been established, the way was cleared for successful cardiographic (and cardio sphygmographic) experiments on man For this consumation it only remained to produce an instrument, which, applied to the chest-wall at the point of sensible cardiac impulse, would faithfully register the movements there, to secure trustworthy representations of the movements of the heart. Cardiograms from the chest-wall of man were first obtained with Marey's sphygmograph, but it was soon found that this instrument was ill adapted to the purposes of cardiography Marey set himself about to devise an efficient cardiograph Retaining the tambour principle and air as the medium of transmission, he constructed, and experimented with, many different forms of instrument, and in turn relinquished one after another as not sufficiently satisfactory Finally he has settled upon one with the mechanism and working of which he expresses himself well pleased[1] It constitutes a part of his new polygraph—an apparatus devised for the simultaneous inscription of the heart and arterial pulse

The cardiograph consists of a receiving tambour, carrying a button or knob on its membrane, and encircled by an outer rim or case in which it is advanced or retracted by a simple device, to secure the required position and pressure in relation to the chest-wall It communicates by a flexible tube with a second or operating tambour whose membrane is connected with a writing lever through an articulated stem attached to its center The instrument is placed with the button of the membrane over the spot of impulse, when the movements received are transmitted by the column of air to the membrane of the second tambour, whose lever amplifies and writes them on the revolving surface of a recording cylinder Excellent and trustworthy cardiograms are obtained with this instrument

The author's compound sphygmograph is also well adapted as a cardiograph It, like Marey's, utilizes the tambour principle, but differs from his, notably, in transmitting by water instead of air It admits of fine adjustments to insure requisite and uniform sensibility It has a manometer tube which is of signal service It is provided with a chronograph It admits of combination with a fellow instrument for purposes of simultaneous inscriptions It is convenient and accurate, and with it the practice of cardiography is a very simple matter Its cardiograms are well delineated and present similar forms with those collected by Marey's. Such are the mechanisms which have brought the science of cardiography to its present status, and which seem to fulfil every requirement for ready and truthful cardiographic observations.

[1] La Circulation du Sang 1881 p 706

THE FORM AND INTERPRETATION OF THE CARDIOGRAM

The typical cardiogram is no longer a strange delineation. It is recognized, in general terms, as a line (read from left to right) quickly rising to a summit, then falling sharply a short distance, then thrown into secondary waves (usually two), then suddenly falling to a point below the beginning, then rising again, first rather quickly, and then more gradually by secondary waves to the point of beginning of the next revolution. In the accompanying figures of cardiac-traces this description is verified. In No. 1, solid line, the main ascent is from A to B, the first descent from B to C, the upper secondary waves from C to E, the main descent from E to F, the second ascent, rather sudden, from F to G, and the lower secondary waves on a gradually ascending line from G to A, the basal point of next main ascent.

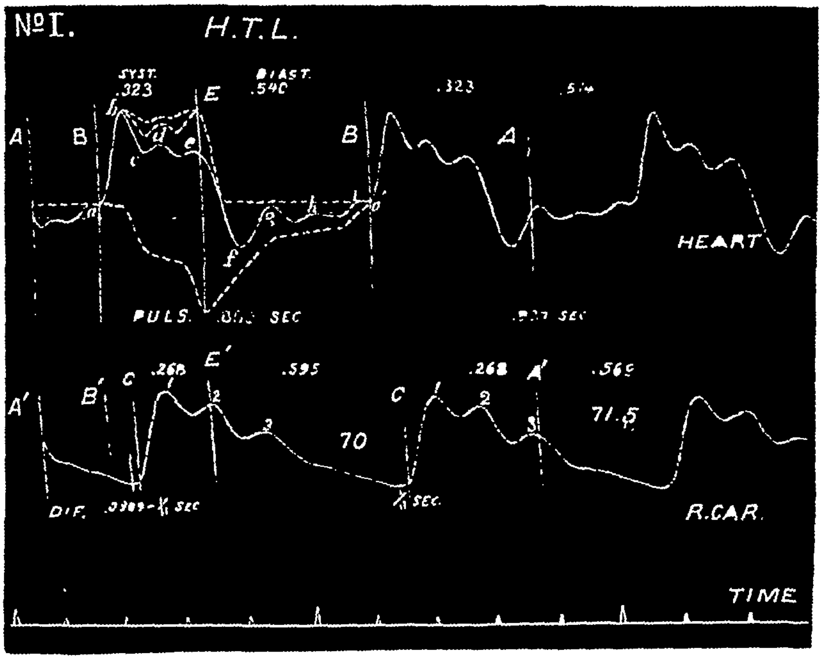

FIG. 1.—Simultaneous traces of the heart and carotid, from a healthy man, aged 28 years, with the time in fifths of seconds, enlarged to double size by photography, and marked for illustration.

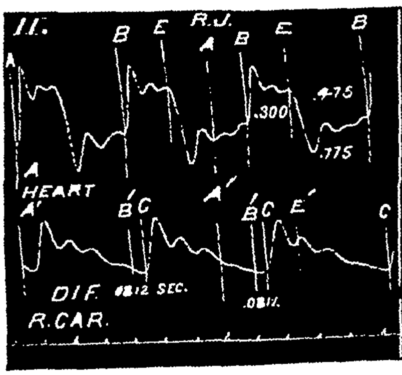

FIG. 2.—Same (normal size) from a healthy young man, aged 20 years.

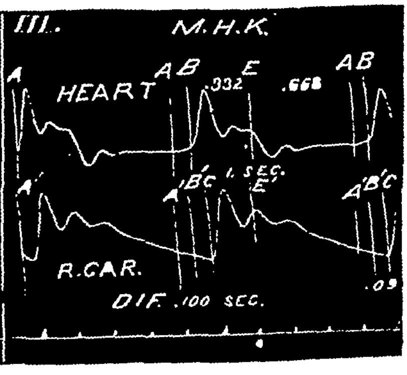

FIG. 3.—Same from another, of the same age.

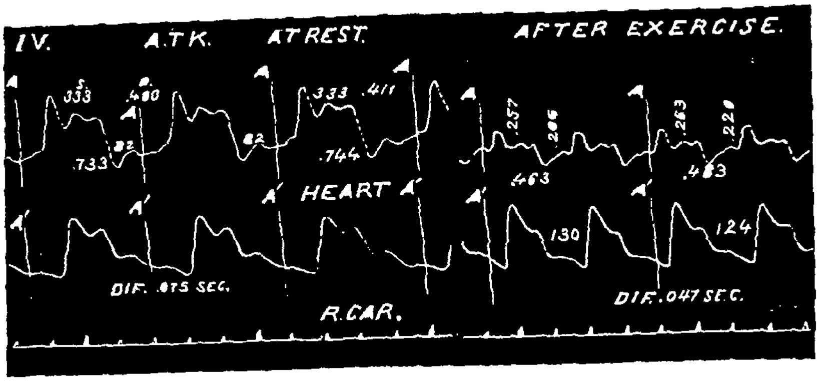

FIG 4 —Same from a man aged 54 years, at rest, and immediately after active exercise

This typical form, however, is often to an extent departed from, even in cardiograms of normally acting hearts The most common variations (intrinsic) pertain to the line between the first summit and top of the main descent, and the line between the bottom of the main descent and beginning of the next main ascent In conditions of disease there are marked variations from the typical normal form

There are also variations (extrinsic) from the instrumental adjustment, which pertain (a) to the velocity of the recording surface, and (b) extent of permitted excursion of the lever The cardiogram will have length according to the first, and height according to the last, but as the true relations are maintained of the different parts of the trace, these variations are not material

Again, there are modifications from faulty applications of the instrument, and from unfavorable apposition of the heart with the chest-wall Either of those causes may produce an inverted, or partially inverted, trace whose reading will be uncertain Moreover, it is true that in certain persons no cardiograms can be obtained in consequence of unusual compactness or thickness of the chest-wall preventing transmission of cardiac movements This personal incapacity is a serious drawback against the universal utilization of cardiography for clinical purposes, but happily most persons are capable of affording good cardiac traces

The cardiogram is a precious document It is the record of the heart's pulsations written by the heart itself Every phase of this record answers to a corresponding phase of the cardiac cycle, and the interpretation is now well understood The line between the bottom of the main ascent and top of the main descent answers to ventricular systole, and the line between the top of the main descent and bottom of the next main ascent answers to ventricular diastole, and the small wave, single or double, which immediately precedes the main ascent, answers to auricular systole The main ascent represents the onset of ventricular systole, the first fall, expenditure of the onset and quick escape of blood into the artery, the upper secondary waves, action and reaction and reciprocal play of blood between ventricle and artery, the main descent, the onset of ventricular diastole, the next rise, filling of the ventricle, the subsequent more gradual rise continued but slower ventricular filling, and the lower secondary waves, if more than accounted for by auricular systole, represent oscillations of the blood between ventricle and auricle whilst their cavities are communicating and walls quiescent

With regard to the small wave immediately preceding the main ascent, this unquestionably belongs to auricular systole, but there has been a question as to the interpretation of the twin wave immediately in front of the latter The author believes that both pertain to auricular systole, the first answering to initial contraction, and the second to the sweep of the blood into the ventricle Yet, while every part of the cardiogram stands for a phase of the heart's action, unfortunately there are two cardiac events which are not distinctly shown in the cardiac trace These are closure of the auriculo ventricular, and closure of the semilunar, valves On listening to the sounds of the heart at the same time its tracing is being produced, it is observed that the first event occurs in the first part of systole and whilst the lever is rapidly ascending, and that the second event occurs in the first part of diastole and whilst the lever is rapidly descending It is thus explained, that the commotion of the onsets of systole and diastole and swift vertical motions of the lever contravene the record of the valvular closures

The mechanism of the cardiac trace, in which the operation of the factors concerned has been more minutely followed, the author has treated elsewhere [1] Let it be stated that the factors are

1 Changes of contraction and of relaxation of the cardiac fibres
2 Changes of intra cardiac blood-pressure
3 Changes of consistence of the cardiac walls
4 Changes of volume of the heart
5 Reciprocal influences between the open ventricle and artery, and open auricle and ventricle

These are the elements which in combination during the rhythmic motion of the heart operate to determine the varying line of its cardiogram It is not difficult to follow these factors and imagine their modules, and from the latter to construct a diagram of the heart's movements, which in reality proves to be the counterpart of the cardiac trace as written by the heart itself.

---

[1] Boston Med and Surg Journal September 29 1881, p 293

It is just, then, to regard the cardiogram as the faithful representative of the heart's pulsations, and to study the latter we have only to study the cardiac traces in which the cycles and phases are shown in their true limits and relations. In this we have a preeminent advantage, for manifestly the cardiac movements evade the touch and the eye for accurate determination. All the qualities of pulsation revealed to the senses, and expressed according to the usual nomenclature, as, strong or weak, quick or slow, frequent or rare, regular or irregular, are distinctly shown in the cardiogram, and, besides, the specific showings of this line relating to the chronometry of the cardiac cycles and events are far beyond the possibilities of the most practiced perception.

FACTS OF CARDIOGRAPHY

Among the facts brought to light by cardiography are

(1) Those relating to the duration of cardiac cycles.—The average duration is easily determined by the usual method of counting the number of pulsations in a given time, but the duration of individual cycles is only determined by measurement of their cardiograms. The rhythm of the heart may appear to our senses perfectly regular, and yet the variation in the length of the cycles be quite considerable. When each cycle writes in succession its beginning and ending, and the distance between is measured by a simultaneously written chronogram, the duration is determined with certainty and precision, and we are enabled to reach results before unknown, and unattainable by ordinary methods of observation. By this method it is demonstrated that in pulsations which appear the most regular and equal the rhythm is continually varying within short limits. There may be a few successive cycles which measure the same, but usually the duration varies. These small variations, although distinctly measurable by the chronogram, are, as stated, wholly inappreciable to the touch, or eye, or ear. In figure 5, the top row of figures shows in decimals of a second the duration and variation of individual cycles, as carefully measured on the chronogram in fifths of seconds, below. Thus we have come to learn that the heart, however regular its action may appear, is subject to an incessant oscillation of rhythm.

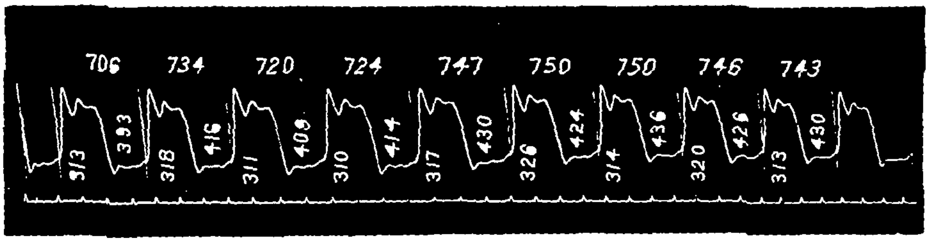

Fig. 5

Not to dwell on the causes of these rythmic variations, the fact of a definite relationship between the respiration and variations of the cardiac cycle may here be mentioned. It has been demonstrated that the cycles of the heart are shorter in inspiration and longer in expiration, the shortening running over into the first part of expiration and the lengthening running over into the first part of inspiration. See figure 6.

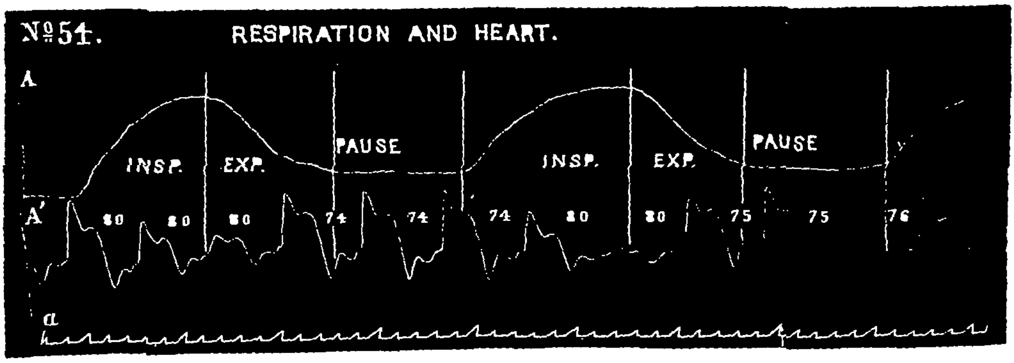

Fig. 6.—Respiration and heart traced simultaneously, with the time, and marked to show the pulse rate of the individual cycles.

(2) *Facts relating to the duration of ventricular systole and diastole* Without cardiography there are no means of determining, even approximately, the duration of the periods of contraction and relaxation of the ventricle, with cardiography these durations are determined with the greatest facility and accuracy The cardiogram, as stated, marks the beginning and end of these phases, and determination of their duration is only a matter of measurement on a horizontal line Concerning these points investigation has brought out the following formula of results

A —With pulse-rate at 75 per minute, (cycle four-fifths = 800 second), the average duration of systole is about 326 second, and of diastole about 474 second

B —In the small variations of cyclic rythm systole usually also varies, but its variations may be either with or against the sense of the variations of the cycles In considerable cyclic variation systole is shorter with short, and longer with long cycles

C —In the small variations of cyclic rhythm diastole usually, also, varies, and in much greater degree than systole, and almost always in the same sense as the cyclic changes In considerable cyclic change the diastolic shortening or lengthening is correspondingly large

D —Systole and diastole may both vary their duration without change of the cycles, in which case the shortening of one will exactly equal the lengthening of the other

In illustration of these statements figure 5 may also be studied The systoles were carefully measured and the diastoles computed by deducting the latter from the corresponding cycles The figures within the divisions express, in decimals of a second, the values found The pulse-rate of the individual cycles of the run varies between 80 and 85 per minute, and the average rate of the nine cycles is 81 5 per minute

(3) *Facts relating to auricle* — Although the theory, that auricular contraction occurred in the latter part of the period of ventricular relaxation, was well accepted, it remained for cardiography to produce indubitable demonstration of the fact, and definitely determine the relative position and time of this event Graphic experiments on animals and on man go to prove that the systole of the auricle precedes the systole of the ventricle by an interval which averages about one-fifth the duration of the cardiac cycle, the proportion, however being less in long, and greater in short cycles In animals the auricular trace, as obtained directly from the auricle, is in form of a pronounced single wave, but in man the trace, as obtained indirectly through the ventricle, is in form of two small waves, as said before The double wave of man occupies the same proportional interval as the single wave of animals

These are specimens of the results of pure cardiography In a word, by it we learn the form and chronometry of the heart's pulsations The facts, if not extensive in range, are such as may be multiplied by every experimentation, and like those of clinical thermometry become innumerable They commend themselves for their positiveness and precision, and as supplying a void in our knowledge of the finer physiology of the heart's movements Besides, they claim our appreciation in that they are essential and preparatory to the richer and more practical developments of simultaneous cardio-sphygmography

SYMPATHETIC OPHTHALMIA WITH OSSIFIC AND CALCAREOUS METAMORPHOSIS[1]

BY FLAVEL B TIFFANY, M D,

OF KANSAS CITY, MO

It is with some hesitancy that I come before this assembly with a paper on sympathetic ophthalmia, a subject the literature of which is so voluminous and opinions so greatly at variance But considering the importance of the subject, the frequency of its occurrence and its direful results, it may not be out of place for me to report some cases which have come under my observation The cases which I shall present are complicated with some ossific or calcareous metamophoses, one having a worm, lanceolatum distoma, of the choroid

Ever since sympathetic ophahalmia was first announced by Mackenzie, the disease has been looked upon as one of the most dangerous and formidable which the eye is heir to Its approach is insidious, and when the flame is once kindled, it is extremely difficult to smother it before great damage is done Plastic exudations have taken place ere the patient is aware that he has any difficulty of the eye, adhesions are formed, binding the iris to the anterior capsule of the lens and the pupilary area is filled or the pupil is occluded and blindness ensues That sympathetic ophthalmia is a plastic inflammation of some portion of or of the entire uveal tract, is quite generally acknowledged In considering the pathology of the disease, it will, no doubt, be agreed that it is a disease peculiar to the uveal tract, and that the ciliary body and parts in near proximity are the first to be involved But when we revert to the etiology of the disease, I am sure that there will be a difference of opinion as to whether it is a transmitted or a reflected affection According to my observations and data collected I must regard the affection as a reflected disease through the medium of the ciliary nerves, notwithstanding Arlt's strong argument in favor of its being a continuation of an inflammation of the optic nerve through the optic commissure, or the assertions of others who claim to have traced the hypothetical microbe of the offending member through the optic nerve to the other eye In support of the theory that sympathetic ophthalmia is a reflected disease and that it is through the medium of the ciliary nerves, and due to diseased filaments of these nerves, and not a progressive inflammation through the optic nerve, I give the following data

1 Sympathetic ophthalmia is a plastic inflammation, a form of inflammation peculiar to vascular tissue not to nerve tissue

2 It is an inflammation of the uveal tract usually

---

[1] Read in the Section of Ophthalmology and Otology at the Thirty Sixth Annual Meeting of the American Medical Association

of the ciliary body, frequently involving the iris and choroid while the retina remains intact

3 In inflammation of nerve tissue it is the neurilemma or medullary portion rather than the axial part that is involved

4 The optic nerve sheath does not enter the eye but passes over on to the sclera, leaving the nerve to enter the eye as a non-medullary nerve

5 The ciliary nerves enter the eye and do not leave their medullary portion until they are lodged in the ciliary region

6 The ciliary nerves go to supply, and are intimately connected with the uveal tract, and ciliary region, whereas the optic nerve has no immediate connection with this tract

7 Were the optic nerve the medium of transmission or propagation of the inflammation by extension, enucleation would not be likely to arrest the inflammation

8 Sympathetic ophthalmia occurs in eyes with completely atrophied, and even cretaceous degeneration of the optic nerve

9 The sympathetic irritation has been arrested by division of the ciliary nerves near their entrance into the sclera, leaving the optic nerve intact

The cases which I wish to present, are interesting and instructive, both as corroborating what has been said regarding the etiology of the disease, and in the specific phenomena of calcareous and ossific degeneration

Case 1 —Charlotte K , a Swede, aged 64, was led into my eye and ear clinic on Sept 30, 1884 With her right eye she could but count figures 16 inches away, while she was totally blind in the left At 15 years of age, while playing on the grass one day, she accidentally discovered that she was blind in the left eye She asked her mother if it was true with other people as it was with her, that if they covered the right eye they could not see, whereas if only the left eye was covered the sight was good? This was the first knowledge her parents or friends had of her blindness She was taken to a physician in Sweden, who told the parents that their daughter had a gray star of the left eye There was no remembrance of her ever having received an injury or of her having had an affection of any kind in the eye, nor had she ever had any pain or soreness there, surgical or medical treatment of course she had not had The sight of her right eye had always been good up to a few weeks previous to her first visit to me Up to that time she had never experienced inconvenience of any kind from this eye At this time, Sept 15, 1884, when milking, the cow switched her tail in the patient's face, striking her left eye with some force, occasioning considerable pain which subsided after a few hours, three or four days subsequently her right eye began to grow dim, the dimness gradually increased up to the time when I first saw her, when, as before stated, she had only a very small amount of vision

Ophthalmoscopic examination revealed choroiditis-pigmentosa, floating bodies in the vitrious, with some slight opacity of the lens Diagnosis Choroiditis with incipient neuclear cataract of R E There was a very dense leucoma of the left, which would not permit an examination of any of the internal structures The cornea also had centres of cretaceous metamorphoses, the intra-ocular tension was considerably increased especially at the posterior portion where the eye firmly resisted any pressure I regarded the eye as an old glaucomatous eye, and the source of the irritation to its fellow, and accordingly urged immediate enucleation, notwithstanding there was no pain or soreness, nor ever had been except for the short interval succeeding the injury from the cow's tail

As I enucleated the eye, it was accidently dropped and fell to the floor, giving a sound like that of a stone or bone Upon making a transverse section, the following macroscopical conditions were found Cornea hypertrophied to several times its normal thickness, entirely leucomatous with extensive calcareous metamorphoses The crystalline lens was quite calcified in situ, the anterior chamber obliterated and iris in juxtaposition with the cornea, the retina completely detached, and coarcted by an osseous cup, which occupied the whole fundus of the eye (with the exception of that part opposite the optic nerve) and extending in part to the ora serrata The opening at the optic nerve, through which passes the retina, measures a fourth of an inch in diameter, and at this part the plate or cup of bone is at least a fourth of an inch in thickness, while it gradually decreases in thickness as it approaches the ora serrata In Dr Knapp's able article on "Bone Formation in the Choroid," he asserts that these ossific deposits of the eye are only found in the choroid, and that they invariably begin in the inner or capillary layer

In making sections of different parts of the choroid, I find that this case bears him out in the assertion that the ossification begins in the capillaries, but, instead of its being near the ora-serrata or ciliary body in the case under consideration, the ossification evidently began near the entrance of the posterior ciliary nerves and arteries, where the cup is the thickest The osseous formation seems to be wholly confined to the inner layer of the choroid, involving more particularly the radicals or capillaries

Dr Alfred Voorhies speaks of a bony formation of the crystalline lens (no ossific deposit elsewhere) He claims to have found in his specimen Harvasion canals, canaliculæ, and lacunæ, but he does not attempt to show how the bone was developed, and in what way the canals and canaliculæ were formed If the lens, or even the capsule, possessed blood vessels, we might more easily account for the phenomenon, or, in other words, we can account for bone formation in vascular tissue, where there is constantly an interchange of fluid, but even here we do not expect to find the same structure as in the physiological formation of bone, for how could we have Haversian zones or lamellæ canals, and canaliculæ, without, first, cartilaginous tissue with its cells surrounded by zones and covered by vascular perichondrium

Turning to the microscopical examination of the case under consideration we find that it illustrates forcibly the hypothesis that Dr H Knapp makes prominent in his article, that ossification always begins in the capillaries

Sections of this specimen show canals, lacunæ, and osteoblasts, but the Haversian zones or lamellæ do not appear How could they without a previous cartilaginous skeleton to build upon? Another point of interest is the *time* of development of the osseous growth From the fact that the patient was blind of this eye from the time that she was 15 years old (possibly from birth), and has now attained the age of 64, the bone may have been been many years in forming The bone formed all around the optic nerve, crowding against it, even cleaving the retina from the choroid throughout its whole extent Yet no sympathetic ophthalmia was produced until the bone had reached the ciliary region, a fact going so far as one case can, to prove the theory that sympathetic ophthalmia is a reflected, not a transmitted disease

After enucleation this patient's vision was increased to $^{20}/_{70}$ and the symptoms of hyalitis passed away I have not seen the patient for several months, and do not know the condition of the cataract

Case 2 —Kate B , aged 20, visited me May 21, 1881, for an affection of the right eye The following is the history as given by herself "When a child in school I was troubled with pain in my eyes, especially in the night The pain was also severe through the temples and over the brow, this pain was intensified by close application to study One day I was kept after school to learn a lesson in geography, which I had failed to get on account of this severe pain, the lesson required close looking, being a map lesson I told the teacher that my eyes pained me so that I could not study, but she insisted on my having my lesson then and there I went home that night with a terrible pain in my eye, which lasted for weeks I was unable to attend school or read a word for two years, at the end of which time I attempted to resume my school work, but my eyes troubled me so that I was unable to attend regularly I went to school, off and on, for two years longer, when I was obliged to desist from all study In the winter that I was 16 my health was very poor, and the pain in my right eye was almost constant My eyes were then crossed Four years later an operation was made on my right eye for the cast After this operation, the eye was much worse "

When Miss B visited me, I diagnosticated secondary cataract in the right eye, with posterior synechae, and in the left, a high degree of hypermetropia I made an iridectomy of the right, and corrected the hypermetropia of the left eye In a few months I made keratonyxis of R E The eye did very well for a time, when repeated paroxysms of glaucomatous pain appeared, destroying entirely the sight There were at this time symptoms of sympathetic ophthalmia in the left eye Three years ago last Christmas I enucleated the right eye

Upon cutting the globe open I found an ossific deposit in the choroid, embracing about one-fifth of this membrane, at the fundus near the macula lutea The portion of the lens which had not been absorbed, was calcified After removing the eye there was considerable hæmorrhage, which gave some trouble in controlling, and for which I tamponed the orbit with a sponge, leaving it in over night The next day when I attempted to dress the orbit, I found to my surprise that sponge-grafting had taken place, so firmly did the sponge adhere to the stump, that I was obliged actually to tear it away, leaving some small bits in the wound Ever since the removal of the eye the patient has suffered more or less pain in and about the orbit, abscesses would occasionally form in the conjunctiva of the stump, discharging into the orbit and through the nose The periphery of the orbit has always been very tender So great has been the hyperæsthesia, that the patient has never been able to wear an artificial eye with any comfort. The pain and tenderness of the stump and surrounding parts have always been increased during the catamenia, and for the past year these periodic paroxysms have assumed a much graver aspect than previously, the pain no longer being confined to the right side, but frequently attacking the left eye also, and culminating in severity at the occiput, or base of the brain While the pain lasted the patient would complain of nausea, and of seeing a halo of prismatic colors when looking at the light of a lamp, great dimness of sight In fact many of the symptoms of glaucoma were present

Regarding these symptoms as pathognomonic of sympathetic ophthalmia, and looking for the cause in the cicatrix of the stump of the eye removed, I determined to excise the cicatrix accordingly, Feb 6, 1885, I resected a portion of the stump, since which time the patient has not suffered the least pain in the empty orbit, and although there have been now and then slight twinges of pain in the left eye, no paroxysm has occurred, nor has there been any dimming of sight I think, therefore, we may conclude that the source of the irritation was located in the cicatrix of the stump, where, probably, there was entangled filaments of the ciliary nerves, upon whose liberation the symptoms of sympathetic ophthalmia immediately vanished

Before concluding, I wish to call attention to another interesting specimen of ossific metamorphosis of the eye In Dr H Knapp's article on "Bone Formation," he emphatically states that the choroid, or the uveal tract, is the only part of the eye which is susceptible to ossific metamorphosis In this specimen, I think you will agree with me that there is at least an apparent bony formation in the sclera, embracing a rim nearly half an inch in width, in the region of the sclero corneal junction, while the uveal tract is entirely free from the slightest ossific deposit

In the fundus of this eye near the optic nerve we find a worm, about a half inch long, embedded in the choroid even to the sclera I am sorry to say that I have no history of this eye, as it was not cut open at the time of enucleation, but placed in alcohol for future examination I only know that it was diagnosed as a glaucomatous eye, and removed to check imminent sympathetic ophthalmia

A CASE OF MEMBRANOUS OCCLUSION OF THE POSTERIOR NARES, WITH OPERATIONS BY THE GALVANO-CAUTERY[1]

BY W E CASSELBERRY, M D ,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS CHICAGO MEDICAL COLLEGE LECTURER UPON LARYNGOLOGY AND RHINOLOGY PRACTITIONER S COURSE 1885 CHICAGO MEDICAL COLLEGE PHYSICIAN TO THE THROAT AND CHEST DEPARTMENT SOUTH SIDE DISPENSARY

It is a source of much relief and gratification to discover the fundamental cause of an obscure chain of symptoms, and when enabled to effect an immediate removal of the cause and thus a radical cure of the disease, we experience a sense of rejoicing which repays us, abundantly, for the many disheartening cases necessarily encountered

Mr E , æt, about 40, native of Russian Poland, has suffered during the past thirteen years from an obstruction of the left nasal chamber Thick, viscid, and foul muco purulent crusts accumulated in the naris and naso-pharyngeal space, which he could neither expectorate nor evacuate by "blowing the nose," because of the impenetrability of the nostril to currents of air Partial occlusion, also, of the right nasal chamber necessitated frequent and prolonged resource to mouth breathing, and he has suffered in consequence from atrophic pharyngitis and laryngitis, with painful deglutition, cough suffocative paroxysms, etc

Deafness in the left ear and annoying tinnitus aurium have long been prominent symptoms Most violent paroxysmal headaches, constant soreness upon the top of the head, vertigo, especially upon stooping, and various indescribable cephalic sensations of a most distressing character, have served to render life literally miserable He has been treated for consumption, bronchitis, catarrh, neuralgia, rheumatism, and other complaints, a rhinoscopic examination never having been made His symptoms continuing to grow in severity he consulted, at length, my friend Dr R O Babcock, of this city, who kindly referred him to me

Status Præsens —Mr E is fairly well proportioned His face is not really emaciated, but it has a pinched expression indicative of constant suffering His temperature and pulse are normal By reflected light the pharynx was seen to be covered with a foul, viscid, muco purulent substance, continuous in descent from the naso pharyngeal space The expired air had imparted to it a disgustingly fetid odor On rhinoscopic examination the naso pharynx was found to be filled with foul and rotten crusts, which necessitated thorough removal as a prerequisite to further inspection of the parts While using the post-nasal syringe for this purpose, I noticed that only a minute quantity of fluid passed through the left nostril, and none emerged unless the exit of the right side was held closed

After syringing, an imperfect image only was obtainable—as the patient gagged upon the slightest provocation—sufficient, however, to discern an almost total occlusion by *something* of the left choana Efforts to pass a probe through from the anterior aperture failed, nor would Bellocq's canula or a Eustachian catheter penetrate, all striking an obstruction far back described, by the patient, as a tender point The finger introduced *per os* felt an impediment in the left posterior aperture

On the following day I employed, successfully, Voltolini's uvula holder, to withdraw the soft palate from the pharyngeal wall, and obtained a much better view, and by the third day, the patient had become so tolerant to instrumental manipulation that I could get a perfect rhinoscopic image A tense membrane covered the left choana almost completely Its free edge was thin and sharp, and approached so near to the septum that, as seen in the drawing, only a very small chink remained between it and the septum narium The left ostium tubæ could not be seen, the membrane evidently lying behind the Eustachian orifice, and so intercepting its image

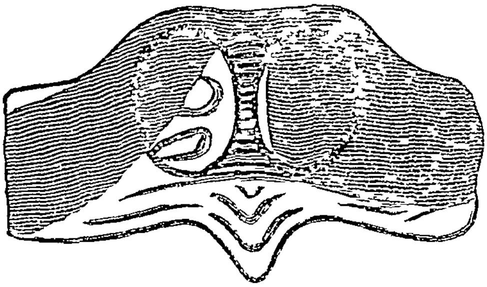

FIGURE 1

Guided by the rhinoscope, I passed a properly curved probe through the mouth, into the naso pharynx, and through the chink between the membrane and septum The edge of the membrane could be pushed backward by the probe, and was then seen and felt to be tense and from one to two millimetres in thickness Efforts were again made to pass several sizes of variously curved probes and bougies through the naris from the anterior aperture into the pharynx, and finally a small Mercier urethral catheter penetrated the chink and emerged into the mouth

The choana upon the right was partially covered by a membrane which extended about half way across the aperture As seen in the drawing, Fig 1, it intercepted the view of the superior turbinated body, the outer half of the middle turbinated body, and the right ostium tubæ This membrane was much thicker and less tense than that upon the left side

Treatment —Incision and consequent removal of these membranes was, evidently, the only effective remedy, and the galvano cautery knife electrode suggested itself as the means best adapted to the end The patient was practiced daily for one week in the use of the rhinoscope and introduction of instruments A flexible silver probe with a handle attached, was bent by numerous trials to exactly the proper curve to pass readily, *via* the mouth and naso-pharynx, into the chink upon the left side and to pick up the edge of the membrane A straight knife electrode was then made to conform to the same curve, and lastly, this instrument, with all attachments, handle, cord and battery, made several trial trips to the desired locality

---

[1] Read before the Chicago Medical Society, July 20, 1885

First Operation, Dec 13th, 1884 All being in readiness the patient held his own tongue by means of Turck's tongue depressor With the left hand I held a small rhinoscopic mirror in position and, guided by the image, introduced the properly curved electrode, holding the handle in the right hand, the cords coming over the right shoulder from Flemming's galvano cautery battery With this instrument one can make and break the current either by means of a treadle or by a button in the handle, but in order to avoid all unnecessary finger or pedal movements, as tending to unsteadiness, an assistant was in readiness to turn on the current at the battery I introduced the knife end of the electrode, one half inch long, through the chink and pressed its edge against the membrane backwards The patient at this moment retracted the soft palate shutting off all vision for a moment, but thanks to previous training, when told to relax all, he let the velum fall, again bringing everything into view At a word the current was made at the battery, the knife end became, in an instant red hot and the membrane was incised without bleeding and without sufficient pain to cause the patient to wince In another instant the current was broken and the electrode, cooling in a few seconds, was withdrawn

On examination I was myself somewhat astonished at the thoroughness of the work,—the size of the aperture produced I had hardly expected to accomplish so much, but the matter is readily understood The membrane being tense at its edge, upon incision it retracted from each side leaving an opening the size of which is represented in the accompanying drawing

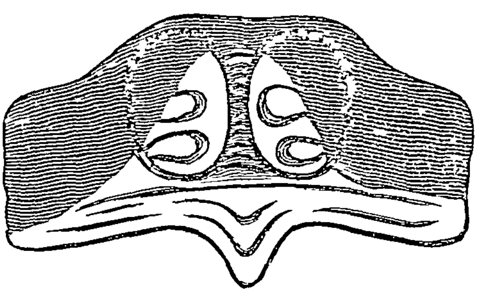

FIGURE 2

The delight of the patient when he discovered that he could again breathe through that nostril was a pleasure to behold, and from that moment he has been completely relieved of all cephalic symptoms, including the left sided deafness

I found the floor of the nose, the septum and the turbinated bodies, thickly incrusted with horribly fetid cheesy masses, the accumulated, decomposed and dessicated secretions of years These were so firmly adherent that they could be detached only by means of a probe during a period extending over several days Their presence for so many years served to excite a bad naso pharyngeal catarrh which, since the removal of the cause, has vastly improved under treatment, but as the disease in the pharynx, and elsewhere to a less extent, had progressed to the atrophic stage, complete alleviation of all catarrhal symptoms is scarcely to be hoped for

On Dec 19th, I operated a second time, passing the electrode beneath the remaining edge of the membrane incising and still further enlarging the aperture After a third operation on Dec 29th, the left ostium tubæ became visible in the rhinoscopic mirror, the membrane having been so far removed as to cease to cover the Eustachian orifice, and two or three more slight touches served to completely obliterate the occlusion Upon the right side four similar operations were performed with a like satisfactory result so that now both posterior nares are widely patent and in an approximately natural condition

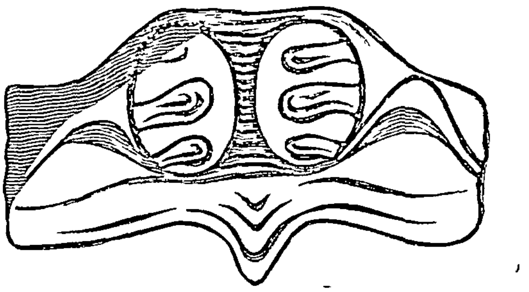

FIGURE 3

It is probable that atresia of the posterior nares is by no means so rare as the few reported cases and the omission of all mention in many treatises might lead us to suppose I have seen the reports of but two cases occurring in the adult one by Voltolini,[1] in which prolonged suffering had been occasioned by a total occlusion of the right choana, the condition being revealed finally upon rhinoscopic inspection, and its removal accomplished by the galvano cautery, the other by Pomeroy,[2] of complete osseous obstruction of the right nostril occasioned by a process of bone extending from the posterior extremity of the inferior turbinated body The operation in this instance was by means of the burr-drill and surgical engine, the bony plate being thus perforated

Records of cases occurring in infancy are more numerous, doubtless because the active interference with the nursing function necessitates one of two things,—either a correct diagnosis and an operation, or death and an opportunity for post-mortem examination Ronaldson[3] reports the case of a female child who died very soon after birth from inability to breathe through the nostrils The posterior nares were found to be occluded by a thick membrane Luschka's[4] case occurred in a female child and the openings were closed by bone Opportunity for an autopsy offered also in this instance The bony framework was formed on both sides from the horizontal plate of the palate bone, extended upwards to the inferior face of the sphenoid bone and to the median line joining its fellow of the opposite side Betts[1] reports a similar case in a fœtus of seven months

Cohen recognized the lesion in a young infant troubled with difficulty in suckling, dyspnœa and frequent suffocative paroxysms He operated and saved the life of the child Emmert[3] operated successfully on a boy seven years old, who had bony occlusion of both choana He had been nourished only with great difficulty when an infant, and he was subject to frequent suffocative attacks Wilkinson,[4] also, reports a similar case in a patient six years of age

In all of these cases the malformation was congenital, and it is most likely that such is true in the case of Mr E He has never suffered from any violent acute or chronic inflammation or ulceration sufficient to develop adhesions, even if the lesion were of the nature of an adhesion, which it is not Moreover, it is difficult to conceive of the complete development of such membranes *extra utero*

But he experienced no inconvenience until thirteen years ago Upon this point he has been carefully interrogated, and we must seek an explanation Is it not probable that in earlier years the membrane upon the left was relaxed and less complete, similar in condition to that which now existed upon the right, there remaining upon both sides apertures sufficiently large for all practical purposes? and that later it underwent contraction, became thinner, tense, and sufficiently extended to cover the choana? The left membranous fold was composed chiefly of a duplicature of mucous membrane, with possibly some connective tissue and muscular fibres interlying in the thicker portion towards the outer border The right structure contained considerable muscular tissue As no osseous malformation existed, it is probable that the membranes sprang simply from the soft parts Upon the left the attachments were, apparently, to the mucous lining of the superior posterior edge of the vomer, the inferior surface of the body of the sphenoid bone, the left pharyngeal wall behind the Eustachian orifice, and the superior posterior surface of the velum palati Upon the right they included only the inferior surface of the body of the sphenoid and the right pharyngeal wall behind the Eustachian orifice

The means employed to effect the removal of the membranes deserve some consideration It is but one of many cases of nasal and pharyngeal surgery wherein I have found the galvano cautery of the utmost utility I do not say that it was impossible to have made the incision with a properly constructed bistoury, but to have done so from behind would have been a difficult if not dangerous procedure, and if attempted from in front one must have worked in the dark The galvano cautery electrode being a dull instrument, could be introduced, withdrawn and reintroduced, without danger to the patient from gagging, until the point was brought into exactly the desired position, when in an instant it could be converted into a cutting instrument, and in another second reconverted into its harmless self to be withdrawn Little or no bleeding results, and the pain is infinitely less than would be supposed

The battery which I employ is manufactured by Otto Flemming, of Philadelphia, from suggestions furnished by Carl Seiler It has many advantages over any other that I have seen

70 Monroe St , Chicago, July, 1885

NEURO-RETINITIS ALBUMINURICA[1]

BY W CHEATHAM, M D ,

LECTURER ON DISEASES OF THE EYE, EAR AND THROAT IN THE UNIVERSITY OF LOUISVILLE

Having seen ten cases of this affection in my ophthalmic practice, I have thought it well to report them to this Society, with illustrations, by means of the magic lantern, of the appearance of the fundus oculi with its changes, as distinguished from the normal eye The ophthalmoscope in the diagnosis of diseases of the kidney I regard as an extremely important instrument In five of the ten cases I have seen, no disease of the kidneys had been suspected by the family physicians, although they were all thoroughly well-informed practitioners

Case 1 —While examining school children in New York to see the effect of study on their eyes, one of them, whose vision was $^{0}/_{0}$ or perfect, had the most marked neuro-retinitis albuminurica I ever saw His physician, one of the leading men in New York, had never suspected kidney trouble, on examining the scholars two years later, he had in the interval died of disease of the kidneys

Case 2 —Some years ago, during the life of Dr Foree, of Louisville, he called me in to see a married woman, at about the seventh month of her pregnancy Rapid loss of vision was her only symptom The ophthalmoscope showed most marked neuro retinal changes indicative of disease of the kidneys Convulsions and death soon followed

Case 3 —Mrs R , a primapera, in her eighth month of pregnancy, lost the vision of both eyes rather suddenly there was not even perception of light when I saw her Early in her ninth month of pregnancy she gave birth to quite a large child The ophthalmoscope revealed neuro-retinal changes, such as are seen in affections of the kidney Vision in one eye commenced to improve rapidly after her confinement, and continued to do so until it was perfect Vision of the other eye remained zero, the nerve and retina becoming atrophied

Case 4 —Symptoms and results as in case 2

Case 5 —Miss B , æt 14, had noticed for some weeks that the sight of her left eye was failing Dr B , her physician, referred her to me Her vision in left eye was zero Vision of right eye = $^{20}/_{20}$ Fundus perfect Fundus of left was a perfect picture of neuro-retinitis albuminurica She had no œdema of extremities or face, no headache, no nausea, no pain in the small of the back. Pulse 121 and full, respiration 20. She suffered from dyspnœa on going up stairs rapidly. I referred her back to Dr. B. for further examination. He found both albumen and casts in urine. Dr. B. put her on treatment, milk diet, etc. In five weeks the fundus had improved wonderfully, and vision increased to $^{5}/_{10}$, or half of perfect. Miss B. is a very well developed girl, and had had no sickness recently.

[1] Read before the Kentucky State Medical Society, June 25 1885

In all of these cases the first symptom was the loss of vision, with no other symptom that would have attracted the attention of the physician. Many cases have been reported in which the eye symptoms preceded for some weeks the albumen and casts. Of course in these cases the ophthalmoscope is invaluable. Such cases would indicate that the disease is improperly named. They appear also to support Sir William Gull's theory, that Bright's disease originates as a disease of the arterioles, not only of the kidneys, but of the whole circulatory system. There is a case on record in which the left eye alone, of a patient 43 years old, was affected with all the subjective and objective symptoms of parenchymatous nephritis. At the autopsy, the right kidney was absent, its place being occupied by a hypertrophied lobe of the liver; there was nothing to indicate that there had ever been a right kidney except the presence of a supra renal capsule. The left kidney (remember it was the left eye that was diseased) was in its normal position, was considerably hypertrophied, and had the characteristics of the large white kidney of parenchymatous nephritis. Cases of unilateral retinitis albumenurica are not very common. Case 5 is the first I ever saw. The right eye of this patient is, and has been all along, perfect. Schweigger says: "It always affects both eyes, although not always in the same degree." The changes observed in retinitis albumenurica are considered by Liebreich as so constant in this form of inflammation, that Bright's disease may be diagnosticated with certainty by the ophthalmoscope.

Sometimes in what is known as descending neuritis, the symptoms very closely resemble those of nephritic retinitis. What are the changes seen in nephritic retinitis? Besides the usual symptoms of neuro retinitis, such as hyperæmia of nerve and retina, we find grouped around the macula lutea, white spots arranged in a stellate form, and looking very much as if some one had splattered white paint on the surface with a brush; this is in the earlier stages. Later the spots unite in a large, white glistening spot, surrounding the optic nerve, often not extending entirely to it, and reaching as far as the equator. Dipping in and out of this white substance, can be seen the blood-vessels, which have here and there broken down, resulting in hæmorrhages into the retina.

The three symptoms most characteristic of nephritic retinitis are: the bright stellate spots around the macula, the white mound surrounding the nerve, and the spots of hæmorrhage. The choroid and vitreous are often involved. Vision varies greatly. One of the worse cases I ever saw (Case I) reported, had perfect vision. Vision is very rarely reduced to zero. Schweigger says: "This form of retinitis may be developed in all cases in which albumenuria has existed for some time. This is most frequently the case in chronic Bright's disease; still the existence of retinal disease has also been demonstrated in connection with croupous nephritis, with amyloid degeneration of the kidneys and in the passive hyperæmia of the kidneys in pregnancy."

Retinal disease occurs in about seven per cent. of all cases of Bright's disease. Occurring most frequently in the most insidious form of Bright's disease (the cirrhotic), it makes the ophthalmoscopic examination, therefore, the more important.

Let us for a moment glance at the pathology of the changes observed in retinitis Brightii. The hæmorrhages are the result of fatty degeneration of the coats of the vessels. The striated appearance of the infiltration into the retina and optic nerve is the result of the formation of the connective tissue that support the nerve fibers. The large, white surface surrounding the optic nerve, and the stellate spots around the macula, depend upon fatty degeneration of the cellular and connective tissue elements of the retina, more especially of the external granular layer, with exudation into the retina. The stellate appearance at the macula, is due to the peculiar anatomical arrangement of the radial connective tissue fibres at the yellow spot. The optic nerve fibres also often undergo sclerosis, and are seen in groups of small glistening spots, which are of great importance, especially as to prognosis. They closely resemble the spots of connective tissue fatty degeneration, but are differently located, being more superficial, or in front of the blood vessels, the latter being in the external granular layer, or back of the blood vessels. Often changes occur in the nerve elements of the internal layers. The cheroidal changes observed are round masses of sclerosed substance, corresponding to the degenerated portions of the retina (Virchow). A peculiar embolism of the fine ciliary arteries has been noticed. Proliferation of the connective tissue of the adventitial coat of the retinal vessels often occurs, as seen by bright stripes accompanying the vessels.

The connecting link between the disease of the kidney and that of the retina has not been satisfactorily demonstrated. Some have supposed it to be due to impairment of nutrition, others to the urea, and others again to the albumen. There are many cases on record that upset all these theories.

The best prognosis is afforded in these cases, following the exanthemeta, typhoid fever and the advanced stages of pregnancy. No special treatment to the eye is indicated beyond rest and avoidance of bright lights.

CONCUSSION OF THE BRAIN, FOLLOWED BY FATAL MENINGITIS.

BY H. MOULTON, M.D.,

OF STUART, IOWA.

On the afternoon of June 13, two boys, aged each about fifteen years, were fighting each other in rather close quarters, when one drew from his pocket a heavy knife, closed, and with a short, quick, upward stroke, he inflicted in the left temporal region of the other a wound, from which blood poured freely The bystanders, thinking the blow too light to have produced a serious injury, referred the hæmorrhage to the nose When I reached the spot, a few minutes later, blood still flowed encouraged by the injudicious local use of water

Hæmorrhage being checked by pressure, the boy fainted Soon reviving, he was brought to my office, where the wound was dressed The sharp corner of the knife handle had made, not a deep cut, in the mass of temporal muscle, about one inch above the mid point of a line drawn from the external canthus of the eye to the external auditory meatus There was no sign of fracture, nor symptom of concussion or compression, and there was no paralysis The pupils of the eyes were slightly dilated, otherwise normal The boy did not lose consciousness, nor fall or even stagger after the blow He was pale and weak from the loss of blood, complained of slight frontal headache, and vomited once before leaving the office At 6 P M, one hour after the accident, he walked with some assistance to a carriage, and was taken home At this time his temperature was normal, and pulse weak and moderately accelerated During the evening he vomited, had a chill, lasting a half an hour or so, became feverish, and passed a restless night, with some delirium

On seeing him next day, at 9 30 A M, the temperature in the axilla was 104° F, respiration 28, and the pulse not very vigorous at 120 per minute The head ached, the skin was dry, the eyes normal in appearance, and the special senses not perverted The patient was restless in bed, but complied intelligently with all my requests and made known all his wants Owing to the recent free bleeding, depletory measures were not adopted, but cold to the head and sponging of the body were ordered, and a single 5 gr dose of quinine administered

1 30 P M —Temp 104° F, resp 30, pulse 120 Patient was more delirious, and had a mild general convulsion

4 P M —Temp 104 2°, resp 32, pulse 130 Conjunctivæ were now congested, and the pupils of the eyes contracted, but sensitive to light Delirium continued, and there had been occasional spasm of some of the muscles of the face and forearm Large doses of bromide of potassium had been given, and these symptoms soon subsided Six grains of calomel were administered at this time

6 30 P M —Temp 105° F, pulse 130 resp rapid Patient was put into the wet pack, and at 8 o'clock had a temperature of 103 5° F He was now rapidly becoming unconscious, and soon was in a state of complete stupor

During the night, under the use of cold and the ice cap, the temperature ranged from 103° to 104° F The pulse became more feeble, and respiration rapid and shallow There was some tonic contraction of the flexors of the forearm The fæces and urine were passed involuntarily into the bed

June 15, 7 A M —Temp 104 5° F, resp 40 pulse 138 Hands and feet cold, skin moist, and the pupils of the eyes irresponsive to light

10 A M —Cyanosis developed, with the pulse imperceptible at the wrist

At 12 M, 43 hours after the receipt of the injury, death took place from apnœa

The plan of treatment followed was, to reduce temperature by sponging the arms, neck and trunk, and by the wet pack, to reduce temperature and lessen local inflammation by cold to the head, using first simple cold water, afterwards an ice cap, to lessen intra cranial congestion and quiet nervous excitement by the use of large doses of bromide of potassium, and to strengthen the heart by the administration of digitalis begun early Consultation was had during the progress of the case, with Dr J H Kersey

At the autopsy, an account of a former unfortunate circumstance occurring in the practice of another, we were enjoined not to remove the calvarium and limited to an examination at the seat of injury The wound was laid open and found to penetrate about half way to the skull, through the muscles and fascia After dissecting up a flap from before backwards, the skull presented no mark of violence The trephine, applied over the anterior inferior angle of the parietal bone, exposed the dura mater and the branch of the middle meningeal artery uninjured There was no extravasation between the dura and the bone A finger passed in at the opening, and swept around as far as it could reach, detected no sign of fracture of the internal table of the skull The dura was but slightly congested Underneath it were a number of small blood clots which were removed Others were brought into sight by pressing aside the brain substance, but no large ones appeared The pia mater and superficial brain substance were intensely red and congested and tumid

In the light of this limited examination, the conclusion was that the vessels of the pia mater were ruptured by, and a general meningitis followed the concussion, and that this result was favored by great intra cranial congestion, due to excitement and the heat of the day There may have been other injury to the brain which we could not see Mr Holmes would place this among "cases not classifiable " in which the usual symptoms of concussion are absent and hæmorrhage is not sufficient to produce compression, but in which a fatal injury is done, and "some laceration of the brain or extravasation into the membranes appears to have been always found "

Stuart, Iowa, July 8th, 1885

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

THE ELECTRICAL EXCITABILITY OF THE BRAIN —This is a subject on which M VULPIAN made a report to the Académie des Sciences, on March 23 The doctrine of the cortical motor localisations depends on two kinds of experimental proof, one being the effects of destruction of cortical regions, the other the motor effects of electrisation of these regions The latter, the only one which Vulpian has examined experimentally, are of value only when the motor effects in question are manifested in entirely different ways, according as the electrisation is made on the cortical gray substance alone or in the subjacent white substance. This difference in the experimental results is admitted by those who believe in the cortical excitability of the brain. They hold that the cortical layer, in the motor regions, is more excitable than the underlying fasciæ, for a faradic current which is sufficient to cause movements when it acts on the cortical region, the motor centre of the posterior limbs for example, is not capable of causing this same motor reaction when this region of the cortical gray substance is excised and the current is applied to the underlying white substance. Without doubt, says Vulpian, but the operation made to disclose the white fibres diminishes their excitability by the amount of traumatism and hæmorrhage which it causes. To avoid this he excites the white substance by means of a copper wire covered with gutta percha except at its very point, by inserting this through the gray substance, and exciting the white fibres while they are intact. He shows that they are much more easily excited than the cortical layer.

Another difference consists in the fact that energetic and prolonged electrical irritation of the excitable points of the cerebral cortex causes epileptiform attacks, which never occur when these excitations are made on the corresponding white fibres. In such an experiment as the preceding Vulpian has always, by irritating the white fibres, caused a violent and prolonged epileptiform attack, and this even with a current more feeble than that necessary to cause the same reactions when applied to the cortical gray substance. Vulpian therefore thinks that he is authorized in saying that the experimental arguments, by the aid of which it has been attempted to prove the motor excitability of the cortical gray substance of the cerebrum in certain determined points, are deprived of all value, and do not support the hypothesis of cerebral functional localisations. It should be said that the nerve fibres which convey cerebral motor incitations to this or that point may escape from the cerebral cortex without the necessity that this point should be a centre of action of these fibres.—*Revue des Sciences Medicales*, July, 1885.

MATERIA MEDICA AND THERAPEUTICS

PARTHENINE—A NEW REMEDY.—DR. JOSÉ RAMIREZ TOVAR gives, in *La Cronica Medico Quirurgica*, of Havana, the results of his experiments with parthenine, an alkaloid derived from parthenium histerophorus. One of the first cases was a strong and vigorous woman of 34 years, who suffered from an insupportable facial neuralgia, which became worse at a certain hour every day. One gramme of parthenine was ordered, divided into ten papers, one to be taken every hour. She began to feel relief after taking three of the papers, and the next day passed without experiencing the usual exacerbation. Small doses were recommended afterwards to sustain the action of the first doses. She disregarded the advice, and as a result, she returned on the fifth day again complaining of the neuralgia, but this time not so severe as before. A few more doses of the parthenine cured the affliction, for she had no attack during the succeeding five months. Two cases of intermittent fever were also successfully treated with parthenine. A little child who had suffered for seventeen days irregularly from fever, drowsiness and anorexia, and who had derived no benefit from quinine, showed marked improvement in twenty four hours after using parthenine, and in three days the temperature was normal. The results in all of Dr. Tovar's cases have been so striking that he feels confident that parthenine, if it come into general use, will not disappoint the hopes that have been built upon it.—*Therapeutic Gazette*, May, 1885.

MEDICINE

SYPHILITIC GUMMATA OF THE LARYNX.—Syphilitic gummata of the larynx are not so rare as generally supposed; they manifest themselves singly or in a multiple infiltrated form. The epiglottis, the aryteno-epiglottic fold, the arytenoid cartilages, and the inferior vocal cords constitute their seat of predilection. Tobacco, alcoholic drinks, speaking, and singing are the principal causes which determine the localization of gummata upon the phonating organs. These lesions occur with equal frequency in both sexes.

Gummata are either superficial (gummous laryngitis, properly so called) or deep (chondritis, perichondritis). We divide gumma into four stages: of formation, of softening, of ulceration, and finally of reparation. Functional symptoms, and especially signs furnished by the laryngoscope, characterize the the disease during these four periods.

The first stage is characterized by hoarseness, by slight pains, and by a redness and small indurations which are revealed by the laryngoscope. The second stage is characterized by the same signs, and additionally by an engorgement of the cervico maxillary glands and the development of gummata exhibited by the laryngoscope. The third stage is characterized by a puffiness of the region of the neck, by pain, increased on pressure and by deglutition, by hoarseness, raucity of the voice, and aphonia. The laryngoscope shows an ulceration of the larynx of variable extent; its edges are perpendicular, with a peripheric areola and œdema of the aryteno epiglottidean region; the ulcerated base is yellowish and covered with a thick, grayish matter.

Finally, the fourth stage is characterized by cicatrices and all the functional signs which accompany them. The diagnosis is quite difficult during the ulcerative stage of the gumma, because the ulceration may be confounded with all other ulcerations of the larynx. Still the antecedents of the patient, the ganglionic engorgement, the localization of the lesion and of the neighboring œdema, the laryngoscopic examination and, if necessary, specific treatment, will elucidate the diagnosis.

Syphilitic gummata are less serious during the first two stages, and by appropriate treatment their resorption may be effected without any unfortunate consequence Ulcerating gummata are, on the contrary, very grave, not only on account of the immediate functional troubles which they provoke (œdema), but also from the stricture which they may leave as a result

The treatment differs in no respect from the ordinary treatment of gummata in general The results obtained by the administration of the syrup of Gibert will be much more satisfactory when this medicament is promptly given The reparative process may be hastened by cauterizations The œdema may be combated by cauterizations with chromic acid in solution (25 to 50 per cent) and by scarifications

If these means fail, it may be necessary to have recourse to tracheotomy, which, done promptly, gives good results The strictures may be combated by dilatation or by incision (Isambert) and if necessary, tracheotomy —Dr George C Latouphis, *Th de Paris*, 1884, *Journ of Cutan and Vener Diseases*, July, 1885

The Treatment of Epilepsy —Dr Charles K Mills says, in a paper on this subject The way to treat epilepsy medically is to simply have a plan of treatment, and carry it out over a series of months or years I would, for instance, first put a patient upon a single bromide, say ten or fifteen grains three times a day, to be increased until a decrease in the number and severity of the paroxysms was produced I would keep him upon this perhaps for a month, and then use the mixed bromides, or some combination of bromides with other drugs, preferably the bromides, arsenic and conium prescription, watching the condition of the patient, and, if necessary, putting him on cod-liver oil, quinine and iron With reference to nitrates, bromates, etc, there is probably some chemical or chemico physiological reason for their inefficiency The *ites* and *ates* would probably *never* give as good results as the *ides* I further agree with Dr Pepper (*Medical and Surgical Reporter*, January 12, 1884) that close attention should be paid to every point in the daily life of an epileptic—to diet, regimen, rest, and hygiene, but I do not with my present experience, believe that a genuine case of thoroughly-developed epilepsy can be cured, or even greatly benefited without drugs

Among the surgical and external means of treatment which I have successfully used are excision of cicatrix, removal of neuroma, actual cautery, and blistering to the neck or head I do not use counter-irritation to the scalp, but am a strong believer in the actual cautery, used after Brown-Séquard's method, to the nape of the neck —*Therapeutic Gazette*, Feb, 1885

Alum in Purulent Ophthalmia —Mr John Tweedy, speaking of the recommendation of alum solutions to be used on the appearance of any discharge from the eyelids from young infants, says Though alum is one of the commonest remedies for conjunctivitis, its use is, in my opinion, not unattended with danger, whenever there is any chance of the cornea being abraded, eroded, or ulcerated In conjunctivitis, and especially in purulent conjunctivitis, one or other of these lesions is seldom absent The danger is that the solution of alum, gaining access to the corneal cement, will dissolve it, and thereby facilitate perforation of the cornea Other medicaments, equally efficient as alum, are free from this fault—viz, chloride of zinc, perchloride of mercury, boracic acid, etc — *Brit Med Journ*, July 4, 1885

SURGERY

Treatment of Diabetes Insipidus —Of the various drugs which are held to exert a curative influence upon diabetes insipidus, ergot has been successfully employed by various practitioners, such as Da Costa, Macaulay, Williams, and Lacy (*Schmidt's Jahrbucher*, March 10, 1885) Da Costa noted a very decided improvement under its use in five cases, and attributes this effect to capillary contraction in either the kidneys or nervous centres Given in a dose of one to two drachms of the fluid extract three times daily, the drug causes rarely any inconvenience Valerianate of zinc and the tincture of valerian seem likewise to induce a favorable termination of this affection, if persisted in for a sufficient length of time Such is the testimony of Lunin, Prior, and Cole, who used these drugs in a number of instances Kennedy prefers the dilute nitric acid (f ʒ j to f ʒ v pro die in water), though admitting that this drug is apt to cause unpleasant after-effects, which are occasionally of sufficient gravity to forbid its continuation Althaus and Clubbe found protracted faradization of the renal zone or galvanization of the medulla oblongata to also give satisfactory results

OBSTETRICS AND GYNÆCOLOGY

Operative Treatment in Pruritus Vulvæ — Otto Kustner (*Centralbl f Gynäk*, March 14, 1885) gives four cases in which he has obtained a cure by excising the parts which are the seat of the pruritus According to him, in the majority of the cases of pruritus, there is a primitive neurosis, but in many cases it consists of an abnormal irritation, which is secondarily exhibited by the abnormal irritability of the vulvar mucous membrane The ordinary causes of this abnormal irritability are particularly, the products of the catarrhal secretions of the uterus and vagina, as this fluid, by constantly bathing the vulva, produces the first symptoms If called early, the pruritus can be relieved by relieving the uterine or vaginal catarrh But if the catarrh and its resulting pruritus have become inveterate, the pathological irritability of the vulva reaches a point which, even after the cure of the catarrh, through the physiological irritation, the rubbing of the parts against each other, suffice to keep up an insupportable itching This natural irritability is increased secondarily by the modifications undergone by the vulvar mucous membrane, by the development of sudamina, of mucous sclerosis excoriations, eczema, herpes, furuncles etc It is in these cases that the operation is indicated It consists in excising the affected parts, and uniting the lips of the wound by sutures —*Archives de Tocologie*, June, 1885

WHAT SHOULD BE DONE

A Special Meeting of the Committee of Arrangements for the Organization of the International Medical Congress, of 1887, having been called for September 3, it becomes the duty, not only of the members of the Committee, but of all who regard the interests of the profession and the success of the Congress as superior to mere professional pride and prejudices, to aid in securing such action at that meeting as will be satisfactory to all fair minded and honorable members of the profession both at home and abroad. This should be done, not with the idea of compromising with, or conciliating some dissatisfied parties, but simply as work needed to render more complete such parts of the rules as were left unsatisfactory at the previous meeting of the Committee, and to fill such vacancies in the offices of the Congress and of the Sections as have been made necessary by the declination of individuals to serve.

The only two items connected with the rules adopted for the organization and government of the Congress, that require further consideration, are those relating to the membership of the Congress, and an Executive Committee of the same, to perform the duties enjoined in *Rule 6* of the old programme. The membership of the Congress was provided for in *Rule 1* of the original programme, and as adopted and published by the Committee as first organized is as follows:

"RULE 1. The Congress shall be composed of members of the regular medical profession, and of such persons as may be specially designated by the Executive Committee, who shall have inscribed their names on the register of the Congress, and shall have taken out their tickets of admission. As regards foreign members, the above conditions are the only ones which it seems, at present, expedient to impose.

"The American Members of the Congress shall be appointed by the American Medical Association, by regularly organized State and local Medical Societies, and also by such general organizations relating to special departments and purposes, as the American Academy of Medicine, the American Surgical Association, the American Gynecological, Ophthalmological, Otological, Laryngological, Neurological, and Dermatological Societies, and the American Public Health Association, each of the foregoing societies being entitled to appoint one delegate for every ten of their members. The members of all special and subordinate Committees, appointed by the General Committee, shall also be entitled to membership in the Congress."

The only legitimate object to be accomplished by altering this rule, was to guard against the admission of delegates from such State and local Medical Societies as had by direct and persistent action repudiated the National Code of Ethics, and arrayed themselves in opposition to the National and State Medical Societies throughout the country. It is well known that this had been done *only* by the old Medical Society of the State of New York and a few of the County Societies of the same State. Consequently the object sought could have been attained fully by inserting a few words in the second and third lines of the second paragraph of the *Rule* as quoted above, making the three first lines read thus: "The American members of the Congress shall be appointed by the American Medical Association, by *such* regularly organized State and local Medical Societies *as are in affiliation with it*, and also by such general organizations," etc., leaving the remainder of the rule just as before.

There was no necessity for going further and dropping out of the rule all the National Organizations for the cultivation of special departments in medicine, for none of those named in the *Rule* had ever taken any action repudiating the Code of Ethics or any part of it, so far as our knowledge extends. And if the American Membership of the Congress is to be a representative body, consisting of delegates fully representing all legitimate interests of the profession throughout the country, there can be no more liberal and just basis for such representation than that provided for in the original rule, with the added limitation in regard to State and local Medical Societies, just suggested.

After the most mature deliberation we prefer the revision of the rule here suggested, to that proposed by the Council of the New York State Medical Association, at a meeting in Utica, July 7, 1885, which is as follows

"That the American Membership of the Congress be constituted of delegates, who shall be entitled to participate in the business and scientific proceedings, and of members who shall be entitled to participate only in the scientific proceedings of the Congress, that the delegates may be appointed by the American Medical Association and by State and local organizations in affiliation therewith, in the proportion of one delegate for every ten or fraction of ten members of the organizations thus represented, that members of the regular medical profession of the United States may become members of the Congress by registering as such, and taking out tickets of admission"

The objections to this plan are 1st That two classes of members in the same body, with unequal privileges, is not only distasteful to many, but a positive inconvenience in conducting the proceedings in such a manner as to keep up a distinction between the business and scientific matters to be acted upon from day to day 2d That opening the doors to all members of the regular medical profession of the United States, practically converts the American part of the Congress into a mass meeting of that part of the profession living within a radius of one or two hundred miles of the place of meeting, much to the disadvantage of those living at greater distances

We call attention to the foregoing propositions for revising the rule regulating the membership of the Congress, that they may be fairly considered before the next meeting of the Committee, and acted upon as their merits indicate, without the slightest reference to the opinions or wishes of those who have manifestly entered into a concerted movement for the express purpose of factiously obstructing the proper work of the Committee The only other item connected with the *Rules*, requiring attention, is the addition of a provision constituting the President of the Congress, the Secretary General, the Treasurer, and the Chairmen of the Sections, an Executive Committee of the Congress, to take charge of its business affairs and the publication of its transactions This done, and the rule in regard to membership properly adjusted, the vacancies occasioned by the premature declination of those who had deliberately undertaken to obstruct the work of organization, should be, at once, filled with good and true men, who will lose no time in completing all the details for as important and successful a Congress as has ever been held in any of the countries of Europe

THE GAME OF BLUFF AND ITS OBJECT

Evidences that the whole movement of premature opposition to the action of the Committee of Arrangements for Organizing the International Congress, taken at the recent meeting in Chicago, was deliberately planned by less than a dozen individuals even before the Committee met, are accumulating from day to day We are already in possession of enough to obtain a verdict of guilty from any intelligent jury The plan was to follow the adjournment of the Committee, so speedily that no candid or full statement of its doings could reach the profession, by an apparently simultaneous and general denunciation of the Committee and the American Medical Association in the *Medical News*, the *Record*, and the *New York Journal*, being careful to avoid specifying any particulars, accompanied by concerted meetings of as many leading men of well known reputation as could be induced by representations essentially untrue, to join in the movement in three or four chief cities It was expected that these movements, thus suddenly developed, would prove contagious, and would induce so general a declination to serve, under what they choose to call the new organization, throughout the whole country, as to frighten the members of the Committee, or a part of them at least, so sorely, as to cause their resignation

To ensure a more certain and speedy spread of the opposition and increase the number of declinations, letters were speedily if not simultaneously dispatched to the leading appointees and parties interested, in every part of the country, announcing the meeting and the withdrawal of the twenty eight in Philadelphia, and the fact that similar results would certainly follow in New York, Boston, Baltimore and Washington These letters and the editorials in the journals just named, were careful to represent each of these little gatherings as a "meeting of *the profession* of Philadelphia," etc , and to give the confident assurance that the work of the Committee was already condemned by a large majority of the profession of the United States Without positively asserting it, the impression was made that the Committee of Arrangements had put Dr Cole in the place of Dr Flint and Dr Shoemaker in the place of Dr Billings as officers of the Congress, instead of having simply made them Chairman and Secretary of the Committee itself

Such is a brief outline of the scheme, simply a neatly planned bit of ancient Chinese warfare, in which a sudden and tremendous noise was to so frighten the enemy as to make an easy victory certain The first vigorous blow upon the *Gong* in

Philadelphia was to echo first in Boston, Baltimore and Washington, and then reverberate throughout the Union, until the trembling occasioned thereby should reach even to the opposite shore of the Atlantic.

And what was the real object to be gained by all this sound and fury founded on nothing? Was it the real intention of the authors of the scheme to permanently abandon the Congress? "Certainly not," said one of their medical friends in Philadelphia, when in familiar conversation with his companion. "They only signed that protest in order to make two or three *scalawags* who are trying to run the Congress step down and out, and they will do it." "They'll come in again all right. They only did this to get rid of those *scalawags*." It is an old saying, that "murder will out," and so will conspiracies, when their authors make letter writing a part of the machinery used in their execution. Unfortunately for the authors of the present scheme, the *Gong* chosen was one whose sound had already become familiar to the ears of the entire membership of our National and State medical organizations, and consequently it only succeeded in frightening a few editors of medical journals, and disturbing the sleep of some of our more nervous friends. In the meantime the work of organizing the Congress is progressing under the leadership of Austin Flint, Sr., for President, supported by Lewis A. Sayre and Henry F. Campbell of the original committee, and cordially sustained by three-fourths of the membership of the National and State Medical Societies of the whole country. And if the *eminent decliners* are to "come in again all right," they had better be moving in that direction soon, for another forty days will not pass before the Gong they so hastily aided to put in motion will be returning as a resistless *boomerang*, from the pathway of which they may find it difficult to escape unharmed.

DISEASE FROM BAD MEAT.

In another column we give, through the courtesy of the Illinois State Board of Health, the report of Prof. Long, of the Chicago Medical College, on the diseased meat which was spoken of in our editorial of July 25, as having caused severe illness at Momence.

It will be seen that the opinions then expressed as to the cause of the illness are borne out by Prof. Long's examination. It will be remembered that none of the symptoms in those cases were such as could be attributed to the direct influence of micro-organisms, though it is highly probable that bacteria were the indirect cause, by leading in some way, not yet known, to the formation of ptomaines.

So far as we are aware, this is the first case in which ptomaines have been systematically sought for and found by an American chemist. Great credit is due to Prof. Long for the careful manner in which he conducted his analyses in this case, more especially for his control experiments, and for the care taken to eliminate sarkin and kreatinine, which give reactions that might be misleading.

Right on the heels of this report comes the information that an epidemic similar to that at Momence, though more severe, has occurred at Porter Station, Indiana. Within three days, up to August 4, five persons have died, leaving fifteen dangerously ill, and about twenty-five others whose condition is as yet uncertain. The village of Porter is supplied with meat from Chestertown, one mile east of the Lake shore. It has been ascertained that the meat at Chestertown has not been kept in good condition, the night watchman and a physician having testified that the most unpleasant odors were emitted from the place, showing that the meat was in an advanced stage of decomposition. If possible we will give a full report, medical and chemical, of this epidemic in a subsequent issue of the JOURNAL.

SPECIAL ARTICLE

THE DISEASE AT MOMENCE, ILL.

The following is the report to the Illinois State Board of Health, by PROFESSOR JOHN H. LONG, on the Chemical and Microscopical Examination of Poisonous Meat from Momence (see JOURNAL of July 25).

The samples received were numbered 1, 2, 3, 4 and 5, of which 1 and 3 were in alcohol, and 2, 4 and 5 dry. Another sample was placed in my hands by Dr. O. C. DeWolf, Health Commissioner of Chicago, which sample was obtained from the house where the death occurred after eating the meat, and which I shall speak of as No. 6.

Preliminary examinations made with small portions of the meat showed the absence of metallic poisons and worms, the presence of which latter was first reported from Momence. In the chemical analysis I followed the Stas-Otto process, and I will add here that the ethyl alcohol, ether and amyl alcohol used in my extractions were prepared by me especially for toxicological work, and no pains had been spared in making them exceedingly pure.

Samples 1 and 2 were minced and extracted together, 3 and 5 were taken together, and 6 alone. Sample 4 was small and was used only for microscopic tests, to be referred to later. In the first alcoholic extraction from the original meat dilute sulphuric acid was used to acidify the mixture of 1 and 2, and 6, while tartaric acid was used in 3 and 5. The ether extracts from the *acid* water-solution left on evaporation slight residues, which gave, however, no alkaloid reaction. These ether washings were repeated twice in each case, and the final ones were colorless. The

THE AMERICAN OPHTHALMOLOGICAL SOCIETY

WEDNESDAY, JULY 15 EVENING SESSION

DR G C HARLAN reported *two cases of Congenital Paresis of the External Rectus*, and also exhibited and described *Boeck's Sphero cylindrical Lenses*

DR J L MINOR, of New York, reported

THE REMOVAL OF A BIT OF STEEL FROM THE LENS WITH THE ELECTRO MAGNET

M S was struck, one week before coming under observation, by a piece of steel There was a small scar in the cornea, and vision was much reduced There was clearly a piece of steel in the lens, which the doctor desired to remove at once After consultation it was thought advisable to await the development of some symptoms The patient was therefore given atropine and instructed to return if the eye gave any trouble Some time later the eye became irritable, there was considerable ciliary injection, there was haziness, and the tension was increased Cocaine was employed and iridectomy performed The shank of a strabismus hook was touched to an electro magnet, thus making it a magnet The extremity of the hook was then carried into the lens and the piece of steel at once attached itself to it and was removed Thirteen days later the eye had recovered from the operation The lens has not yet been removed

DR R H DERBY reported a case of

MAL-FORMATION OF THE UPPER LID

In this case there was a fissure of the upper lid from the angle of which a portion of skin projected in a peculiar manner

DR A MATTHEWSON, of Brooklyn, reported the

REMOVAL OF EPITHELIOMA OF THE EYE-LID BY APPLICATION OF BENZOLE AND CALOMEL

O D, laborer, 50 years of age, was seen October 3d, 1881, with tumor on the right lower lid This first appeared as a warty growth three years previously Of late it had been rapidly growing, and presented a raw, granulated surface Careful examination by an expert showed it to be undoubtedly epithelioma It was treated by frequent dustings of calomel, after brushing the surface with benzole The tumor entirely disappeared until a few months ago, when a granular spot appeared at one edge of the site of the former growth This disappeared under a renewal of the same treatment

DR H S SCHELL, of Philadelphia, reported a case of

LIPOMATOUS PTOSIS

Under this head the speaker reported four cases of ptosis from excessive accumulation of fat in the upper lids The condition occurred in young women between the ages of 18 and 25 The deformity was symmetrical, the weight of the lid causing it to cover one half of the cornea The excessive fat was removed through a horizontal incision The smallest amount taken away was 35 grains The levator regained power in from one to four weeks In one case it was necessary to repeat the operation

DR WEBSTER FOX, of Philadelphia, reported some

CLINICAL OBSERVATIONS

Case 1 *Congenital Cataract in Both Eyes Successfully Operated on in a Patient Sixty Years of Age* — H H, a negro, aged 60, presented herself at the Germantown Hospital February 4, 1884 Congenital cataract of both eyes was found The use of a four grain solution of atropia produced no dilatation of the pupils, there was simply light perception Shortly afterwards the right lens was removed and the wound rapidly healed At the end of eight days the patient could see, but could not name objects without touching them The lens of the left eye was subsequently removed The effect of the acquisition of sight after sixty years blindness was carefully described by the doctor The lens when removed were found to be of a spherical shape The optic nerve presented an oval outline

Case 2 *Recovery of Useful Vision after Eighteen Years Blindness* —R L, aged 37 years, was injured in the left eye when three years of age Two years subsequently sympathetic ophthalmia developed in the right eye, resulting in qualatative perception of light only An iridectomy was done at the Germantown Hospital in June, 1884 The media were found to be clear When admitted to daylight complained of erothropsia to such an extent that dark glasses were ordered This disappeared in the course of three months A plus 10 D spherical glass was ordered for distant use, and A plus 14 rendered near objects visible Subsequent examination showed that better vision was obtained by a combination of spherical and cylindrical lenses

DR LUCIEN HOWE, of Buffalo, read a paper on

THE PULSATING VARIATIONS OF INTRA-OCULAR TENSION AS MEASURED BY THE MANOMETER

In calling attention to the variations of intra ocular tension some attention also was given to various forms of manometer, or instruments for its measurement The earlier forms consisted simply in a U-shaped tube of glass, connected by a flexible tube to a trocar When the trocar was introduced into the anterior chamber of the eye, the intra-ocular pressure would tend to force the fluid through the tube and show the degree of pressure by a rise in the opposite column of the U-shaped tube This was imperfect, for the reason that when the aqueous humor escaped from the eye, it was at once in an abnormal condition The double manometer described by Grasser and Holzke obviated this difficulty In this, however, there was an imperfection in the trocar, which was rather complicated and liable to get out of order An improvement was accordingly suggested in having a stop cock attached to a needle of the hypodermic syringe, and this the writer found to serve the purpose much better than any other The animal best adapted to this class of experiments is the cat, on account of the deep anterior chamber

In the earlier experiments with the manometer, usual precautions were taken before making the next extraction from the alkaline water-solution, the ethereal washings here were evaporated to dryness, leaving slight residues which consisted of soluble matter from the original meat Small amounts of sarkin and kreatinine may appear here, as I have determined by parallel experiments on other meat

After expelling the dissolved ether I next treated with warm amyl alcohol, as in the process given by Uslar and Erdmann The two liquids were separated in the usual manner, and the process repeated with fresh amyl alcohol The extracts so obtained were evaporated to dryness, and the residues tested These were crystalline in No 6, and in the mixture of 3 and 5, but amorphous in the mixture of 1 and 2, and were completely, though with difficulty, soluble in hot water and alcohol They are colored yellowish red by strong nitric acid, and assume a light reddish color with strong sulphuric acid They give decided alkaloid reactions with phosphomolybdic acid, metatungstic acid, tannic acid, iodide of mercury and potassium, iodine in potassium iodide, but nothing with picric acid

Of the organic bases present in normal meat there are three which respond to some of these tests Kreatine is one of these, but its reactions with phosphomolybdic acid and metatungstic acid are to form soluble crystalline compounds, while I obtained yellowish white flocculent precipitates Besides this, in the several processes of extraction and evaporation small amounts of kreatine could be converted into kreatinine (the reverse action sometimes takes place), and kreatinine, whether so formed or already present, gives certain alkaloid reactions But the combinations with phosphomolybdic acid and metastungstic acid are crystalline, and settle out very slowly, as I have determined in parallel tests (see also Neubauer and Vogel, "Harnanalyse," 8th edition, p 15) Kreatine is much more soluble than the residues I obtained, and although a small amount of it was doubtless present, it could not deceive in the tests Another substance is sarkin, and I am inclined to think the reactions of this body have not been sufficiently considered in the discussion of the detection of animal alkaloids It gives precipitates with phosphomolybdic acid and metatungstic acid which are white and flocculent, but it seems to give nothing with tannic acid or iodide in potassium iodine, at any rate, not in solutions certainly stronger than were those under investigation

The phosphomolybdic acid precipitate with sarkin turns blue on addition of caustic alkali, and slowly dissolves As I obtained a slight blue color when I applied this test, it was necessary to eliminate sarkin before going further Nearly the whole of the residue from the sixth sample was saved for this purpose, and I precipitated the base by the method of Strecker, as given by Neubauer (*Fresenius' Zeitschr* , 1867, p 33), with ammoniacal silver nitrate A very slight precipitate was formed and filtered off, and after freeing the residue from the excess of silver and the ammonia compounds, the tests were again applied Sarkin was absent and the alkaloid reactions seemed as sharp as before, indicating the presence of a body of this character The reactions I have noted in these experiments do not correspond to those of any alkaloid with which I am acquainted, yet I think I am quite justified in affirming the presence of a body of this class It must also be mentioned that the amyl alcohol extracts gave immediate reduction tests with potassium ferricyanide (Brouardel and Boutmy, *Fresenius' Zeitschr* , 1882, p 621)

The small quantities of meat at my disposal rendered the investigation very tedious and difficult, and it is not possible to define the nature of the substance found any clearer than I have done Without doubt it belongs to the class of bodies known as *ptomaines*, but to identify it with anything discovered by Selmi, Schwanert, Brouardel and Boutmy, Gautier, or others, is scarcely possible, as the investigations of some of these observers were carried out on quantities of decomposing flesh as small as I acted upon, and the results obtained were necessarily more or less incomplete Notwithstanding recent remarkable investigations, it is yet too soon to consider any of those bodies as described with absolute certainty, and with others I would say that the whole discussion shows the necessity of extreme caution in toxological inquiries

In addition to the chemical tests described above, I have also made numerous microscopic examinations of cross and longitudinal sections of the meat A number of these were prepared for me by Dr Lester Curtis, of Chicago, to whom I must here express my thanks Sections have been made from samples 1, 2, 4, and 6, and the appearance of these indicates a diseased condition of the meat, different from that of normal specimens which I have examined The decayed appearance is not uniform throughout a section, but is found in spots, and this is perhaps more apparent in cross sections than in longitudinal In the former, groups of fibres can be found which have a loose, honey-combed appearance when seen under a high power It must be said, however, that I have examined many slides in which nothing abnormal could be found In most of the sections I find an abundance of micro organisms, some of which are very small, not more than 001 mm , while others are somewhat oval and have a longer diameter of fully double this They can be found in sections cut from the centres of the several samples, and evidently in as great numbers as in those from the outside

In his report made to the Board, Dr J H Utley states that in one case the meat had been fried in butter, and the symptoms after eating it were the same as in the other cases I consider this an important point, as showing beyond doubt that the micro organisms referred to could not be considered the direct cause of the disease At the temperature which meat frying in butter certainly reaches, all such bodies would be rendered harmless, while we have no ground for believing that substances of alkaloid nature would be made inert by the same process I am therefore inclined to think the micro organisms and poisonous substance may be looked upon as cause and effect, and I consider it probable that the symptoms observed were due to the action of the latter

THE PULSATING VARIATIONS OF INTRA-OCULAR TENSION AS MEASURED BY THE MANOMETER

In calling attention to the variations of intra-ocular tension some attention also was given to various forms of manometer, or instruments for its measurement The earlier forms consisted simply in a U-shaped tube of glass, connected by a flexible tube to a trocar When the trocar was introduced into the anterior chamber of the eye, the intra ocular pressure would tend to force the fluid through the tube and show the degree of pressure by a rise in the opposite column of the U shaped tube This was imperfect, for the reason that when the aqueous humor escaped from the eye, it was at once in an abnormal condition The double manometer described by Grasser and Holzke obviated this difficulty In this, however, there was an imperfection in the trocar, which was rather complicated and liable to get out of order An improvement was accordingly suggested in having a stop-cock attached to a needle of the hypodermic syringe, and this the writer found to serve the purpose much better than any other The animal best adapted to this class of experiments is the cat on account of the deep anterior chamber

In the earlier experiments with the manometer, was noticed that the inter-ocular tension varied with the heart's action In addition to this the writer called attention to the fact that these variations in the pressure, as indicated by the manometer, correspond to pulsations which can be seen with the ophthalmoscope in the vessels in the interior of the animal's eye In other words, if the same thing holds in the human subject, we must infer that when pulsation is seen in the interior of the eye, there is also a variation of intra-ocular tension, although not enough to be detected by the touch, or by an ordinary instrument This connection between pulsation and pressure is a demonstration of the cause of venous pulse in the eye, as explained by Donders It was also observed that after the introduction of the needle there was at first considerable pulsation, but after a short time this ceased, the eye evidently adjusting itself to the unusual condition The experiments referred to were made in the laboratory of Prof Zuntz, of Berlin

Dr Knapp reported

NINE CASES IN WHICH THE ELECTRO-MAGNET WAS USED FOR THE EXTRACTION OF CHIPS OF IRON FROM THE INTERIOR OF THE EYE

These cases were operated on during the last three and a half years In two the chip of iron was located in the iris, in one for two days, causing inflammation, and in the other for 17 years, remaining quiet until recently Both were successfully removed without deterioration of the eye In the seven remaining cases, the foreign body was in the vitreous, had produced cataract, and could not be seen In three cases the attempt to extract them with the magnet failed, and the eyes had to be enucleated In four cases, the chips of iron were brought forth at the first, second, or third introduction of the tip of the magnet In all these four cases, the recovery was smooth All four are still cataractous In two the form, size and tension of the globe is not changed, and the perception of light is good over the whole field In the two others the globe is slightly smaller and softer, and the field of vision defective, corresponding to the wound made for the extraction of the foreign body There was no irritation in any of the four eyes as long as they were under observation

Dr H Knapp discussed the use of

THE ACTUAL CAUTERY IN DESTRUCTIVE CORNEAL PROCESSES,

and cited a number of cases in which its use had been of service, and considered it a valuable measure

Dr Howe had employed this measure in three cases, and the corneal ulcer had been somewhat lessened

Dr E Williams had for the past fifteen years been in the habit of treating phlyctenular ulcers of the cornea by the application of pure carbolic acid, and had found it to act admirably

Dr O F Wadsworth had for several years been in the habit of using carbolic acid for ulcus corneæ serpens and for sluggish, painful infiltrations of the cornea In sluggish infiltration the application is preceded by scraping, and in some cases the simple scraping has been sufficient When the ulcus corneæ serpens had been severe, he did not recall that it had entirely stopped the process In a recent case, in which the acid was applied at the beginning of the affection, three applications checked the disease

THURSDAY, JULY 16, SECOND DAY

Dr W F Mittendorf, of New York, read a paper on

PNEUMOPHTHALMOS, OR AIR IN THE VITREOUS HUMOR

The entrance of air into the interior of the eye will occur at times during an operation, as, for instance, a cataract extraction In such cases the air may get into the anterior chamber, whence it can be removed with ease It is, however, entirely different when air gets into the vitreous chamber Fortunately, this accident is of such rare occurrence that so far no description of it has been given The writer has seen two cases of this kind within the last two years Both occurred in connection with injuries caused by the entrance of foreign bodies into the interior of the eye Such accidents are usually so serious that any complication of them becomes a matter of great interest The first case was that of a young blacksmith who was wounded by a piece of iron penetrating the sclera and lodging in the vitreous humor The foreign body, surrounded by a clot of blood, was found at the bottom of the eye Behind the lens and a little above it, three air bubbles were seen by means of the ophthalmoscope These appeared to be of the size of a small pea, the smallest about as large as a rape seed They closely resembled the air bubble as seen under the microscope, their centres being bright and the outlines well defined and surrounded by a sharp black border Their recognition was not difficult The foreign body could not be removed with the magnet, and it was decided to allow it to remain The eye was carefully bandaged, and the day following it was found that the air bubbles had united and were located at the posterior pole of the lens, the patient having remained quietly on his back some time before the examination While he was in the upright position the air began to rise slowly until it reached the upper part of the vitreous chamber During this trip the bubble looked oval and decidedly pointed at its lower portion, resembling oil globules as they are seen ascending in water Forty-eight hours after the accident, every trace of the air bubbles had disappeared

The second case reported was the result of drilling accident A pretty large piece of stone or iron had perforated the sclera at the lower and outer part of the eye In the semi-transparent vitreous an air bubble of the size of a hemp seed could be seen distinctly

In order to determine the exact appearance of air in the vitreous, the writer experimented upon rabbits' eyes Four of them had air introduced into the vitreous humor by means of a hypodermic syringe, and four were subjected to the introduction of oil, also, by means of the hypodermic syringe Nearly all these experiments were successful The difference between the air and the oil bubble was so marked that they could be readily diagnosed by means of the ophthalmoscope The latter were more highly re fractive, heavier in appearance, and the contour decidedly darker than the air bubbles, which were entirely colorless The conclusions reached by the author were as follows

1 The entrance of air into the vitreous body can occur only after a part of the contents of the vitreous chamber has escaped

2 It is favored by the entrance of a foreign body which makes a large gaping irregular wound of the sclera

3 In order to allow air to enter the vitreous humor, this must either be quite fluid or its anatomical arrangement must have been disturbed by the entrance of a foreign body, or the air must have been attached to the foreign body and be thus carried with it into the eye

4 The air in the vitreous humor appears like an air bubble as seen under the microscope It is more or less round, highly refractive in the centre, and has a sharply defined black outline

5 Oil globules in the vitreous present a similar appearance, but they look heavier, are not perfectly colorless, and their outlines are larger, they are also more glittering in the centre

6 Air bubbles will be completely absorbed within two or three days Their presence is not a source of great danger to the eye Oil globules last longer, but they are likewise non-irritating

DR MYLES STANDISH, of Boston, reported a case of

TUBERCLE OF THE IRIS

The patient was a girl fourteen years of age There was absolutely nothing of a specific character in the history of the patient, her parents or her brothers and sister During the past winter she was confined to bed with intense pain in the epigastrium and ascites, which were attributed by the attending physician to hepatitis No pulmonary lesion was detected At the time she came under observation, the eye trouble had existed for four weeks, but there had not been much pain or photophobia Examination showed the iris attached by its pupillary margin to the capsule of the lens, somewhat atrophied in appearance On it there was a growth, 2 mm in diameter, pink in color, with small vessels on its surface The growth projected from the iris near its ciliary border Various mydriatics were employed without any effect upon the pupil In the course of a month the growth had doubled its size Other growths making their appearance, the eye was removed

Examination after enucleation showed the vitreous, retina and choroid to be normal The lens was somewhat opaque The iris was very adherent to the capsule of the lens along its pupillary border, and also beneath the area of the principal growth There were in all, four growths, but none of them involved the ciliary body The microscopical examination by Dr Ernst, of Boston, showed the presence of giant cells and bacilli tuberculosis He considered it an undoubted case of tubercle of the iris

DR KNAPP had seen growths presenting exactly the same appearance which had disappeared under the use of specific treatment with mercury, even where there was no evidence of syphilis He had never felt warranted in making the diagnosis of tubercle in such cases, although the presence of the tubercle bacilli in this case would seem to confirm the diagnosis

DR C J KIPP reported a case of

CONGENITAL COLOBOMA OF THE IRIS, CHOROID, ETC

The patient was a woman 69 years of age She was first seen four years ago There were at that time no inflammatory symptoms, but a small triangular coloboma of the iris was found exactly in the vertical meridian The tension was above normal The patient had never seen with this eye, but it had never given pain Four years later the patient was again seen, and the eye presented the signs of inflammatory glaucoma The pain had prevented sleep for many weeks The eye was enucleated and healed promptly There was also found a large ectasia of the sclerotic, and over this the choroid and retina were wanting The ectasia extended close to the optic papule There was also a deep kettle shaped excavation of the optic nerve

DR S D RISLEY, of Philadelphia, reported a case of

COLOBOMA OF THE CHOROID ON THE TEMPORAL SIDE

A young physician consulted Dr R for asthenopia There was a considerable degree of myopia in the left eye In the right eye vision was much diminished, — $^{0}/_{80}$ The ophthalmoscope showed a large hiatus in the choroid of the temporal side, the depth of which was 3 D The speaker thought that these cases were comparatively rare

DR MITTENDORF had seen several of these excavations in the outward direction Where the coloboma was so deep it was, he thought, probably a coloboma of the optic nerve sheath with excavation of the nerve A difference of 4 D would indicate a greater defect than would correspond to absence of choroid and retina alone

DR W W SEELY read a paper on

SEROUS EFFUSION IN THE VITREOUS DUE TO MALARIA

He considered the occurrence of this complication not infrequent, and he reported one case of this affection

DR WM F NORRIS read a paper on

GREY DEGENERATION OF THE OPTIC NERVE WITH ABNORMAL PATELLA REFLEX

After an elaborate review of the literature of the subject, the speaker gave the results of his observations in cases in which the patella reflex was increased or diminished, and described three cases of grey degeneration associated with tabes dorsalis which had come under his observation While he did not hold that this symptom indicated beginning tabes dorsalis, yet it was a danger signal calling for rest of the brain and cord, with attention to improvement of the general condition

DR O F WADSWORTH reported a case of

DOUBLE OPTIC NEURITIS AND OPHTHALMOPLEGIA FROM LEAD-POISONING, COMPLICATED WITH TYPHOID FEVER

A boy of 9 years of age had suffered from obscure febrile symptoms for several weeks, and movements of the left eye had been observed to be imperfect When first seen by Dr Wadsworth, there was pronounced optic neuritis in both eyes The rest of the fundus normal Vision was much diminished No lateral movements of left eye could be made, and movement downward was impaired The outward movement of right eye was defective The probable diagnosis was tumor in the region of the pons The movements of the eyes became still more impaired and vision sank The boy developed pretty distinct symptoms of typhoid fever The spleen and liver were both enlarged Lead was found in the urine, and the diagnosis of tumor was then abandoned The treatment was with iodide of potassium The general condition gradually improved The neuritis passed into atrophy, leaving too little vision to count fingers The movements of the eyes were completely restored and the lead disappeared from the urine The cause of the lead poisoning was found to be the presence of a piece of lead pipe in the cistern from which the drinking water was obtained

Dr Joseph A Andrews, of New York, read a paper on

OLIVE OIL AS A MENSTRUUM FOR DISSOLVING COCAINE FOR APPLICATION TO THE EYE

In addition to the occasional benefit from the use of oil dropped into the eye in recent abrasions from burns and in other painful affections of the cornea in which atropia is indicated, cocaine may likewise be serviceable The plan of dissolving the cocaine in oil seems to insure a longer contact of the remedy, and a smaller quantity is required to effect anæsthesia, two qualities of especial advantage in operations on the eye

Neither the salt of cocaine nor of atropia is soluble in olive oil, but the alkaloid of both dissolves readily in the menstruum without the addition of an acid, it being only necessary to expose the solution for a few minutes to a gentle heat in a water bath Castor oil is not a desirable menstruum on account of its irritating qualities, and the oleate of cocaine, for the same reason, is still more objectionable as an application to the eye

Dr E Williams read a paper on

QUININE AMAUROSIS

He reported two cases In the first case, a man took about one ounce in the course of four days This produced total blindness and deafness, but in six weeks he could see as well as ever The hearing had never completely returned, although the quinine was taken eight years ago The field of vision was concentrically contracted in both eyes The optic disks were very white, the calibre of the arteries and veins was reduced, and the smaller capillaries could not be seen

The second case was that of a boy of 14 who had received large doses of quinine, the exact amount not being known He was totally blind four days When examined, the sight was much diminished and the atrophy of the optic disks was extreme, and there was great contraction of the field of vision

Dr Lucien Howe described his method of

MEASURING THE AMOUNT OF ANÆSTHESIA FROM COCAINE

The doctor exhibited the drawing of a kymograph which he had used for this purpose The use of the instrument was based on the fact that irritation of a sensory nerve is followed by a rise of blood pressure The instrument is connected with an artery and the conjunctiva is irritated Cocaine may then be applied and the results on the blood pressure compared

Dr Dennet, of New York, exhibited

AN ARRANGEMENT FOR USING STOKES' LENS FOR MEASURING ASTIGMATISM,

and to avoid the inconvenience of constantly removing the frame from the patient's nose The lens was mounted on a stand and could thus be placed in front of the patient

The following were elected

OFFICERS FOR THE ENSUING YEAR

President, Wm F Norris, M D , of Philadelphia
Vice-President, Hasket Derby, M D , of Boston
Secretary and Treasurer, O F Wadsworth, M D , of Boston
Corresponding Secretary, J S Prout, M D , of Brooklyn

The following

NEW MEMBERS

were elected Drs Chas A Oliver, of Philadelphia, Edward Jackson, of Philadelphia, B Alexander Randall, of Philadelphia, D Pope Walker, of New York, Wm O Moore, of New York, Frank G Capron, of Providence, S M Burnett, of Washington, and Wm T Bacon, of Hartford

The next meeting will be held at New London, on the third Wednesday in July, 1886

STATE MEDICAL SOCIETY OF WISCONSIN

Thirty-ninth Annual Session, held in Milwaukee, June 2, 3 and 4, 1885

The President, E W Bartlett, M D , of Milwaukee, in the Chair

Dr Bartlett's

PRESIDENTIAL ADDRESS,

the title of which was "Yours Fraternally," and which was largely concerned with ethical questions, was referred to the Committee on Ethics for consideration As a result of the discussion arising from this address the Committee reported the following resolution, which was unanimously adopted

Resolved, That the State Medical Society of Wisconsin hereby re-affirms its steadfast adherence to the Code of Ethics of the American Medical Association

Dr W Meacher, of Portage, presented two papers, one on the comparative merits of *Syme's and Pirogoff's Methods of Amputating the Foot*, each of which the reader thought had value according as the patient could or could not obtain an artificial foot The second paper was on *Rectal Surgery, with particular reference to the treatment of Fistula and Hæmorrhoids*

Dr S Marks, of Milwaukee, read a paper on

HERNIA, INGUINAL AND FEMORAL,

making a strong plea for the use of narcotics in cases of inguinal hernia when reduction was difficult, and there were no symptoms indicative of immediate danger The experience of the last fifteen or twenty years had greatly changed the speaker's views as to the propriety of early operation in such cases, and whereas formerly, he would have operated promptly on failure of the efforts at taxis, now he would push opiates for twenty-four hours or more, keeping his patient fully under their influence, and using taxis from time to time Of course he would not advise delay where there were fæcal vomiting and other urgent indications of a necessity for operating, neither would he advise waiting in case of femoral hernia after attempts at reduction had failed Under such circumstances he would operate at once, but where danger was not imminent in the inguinal form of the accident he fully believed that he had proved the value of narcotism and delay in many cases

Dr La Count, of Chilton, exhibited a

FEMUR FROM A CASE OF AMPUTATION FOR OSTEO MYELITIS

The bone showed clearly the characteristic effects of the disease and the manner in which adjacent joints became involved

Dr G F Witter, of Grand Rapids, showed a photograph of an

INFANT SUCCESSFULLY OPERATED ON, AT THE AGE OF FOUR WEEKS, FOR HARE-LIP AND CLEFT PALATE

The facial deformity was very marked and there was great difficulty in administering nourishment, hence the necessity for early interference He had never before performed the operation on so young a child, but in view of the degree of success attained in this instance he thought that he should hereafter favor early operation in similar cases

From the Committee on Obstetrics and Gynecology, Drs Armstrong, Davies and Stalker presented papers Dr Armstrong reviewed the progress made during the past decade, especially in *Surgical Gynecology* Dr Davies discussed the *Ignorant Use of Ergot* at the hands of midwives in obstetric cases, citing a case within his own experience in illustration, and Dr Stalker presented an account of a *Case of Arrested Development*, with photographs of the fœtus

From the venerable Dr Harmon Van Dusen, of Mineral Point, who has been for thirty years an active member of the Society and has filled the Presidential chair several times, and who, until prevented very recently by his great age, has never failed to honor the annual meetings by his presence, the Society received as a souvenir the diploma by which, nearly sixty years ago, he obtained entrance into the ranks of the profession The somewhat quaint document, which was issued in 1826 by the Onondaga County Medical Society, of New York, was presented on behalf of Dr Van Dusen by Dr Whiting, of Janesville The Society accepted the gift and voted that it be placed in the rooms of the State Historical Society at Madison for safe keeping, and that the thanks and love of the association be conveyed to Dr Van Dusen

Dr J M Dodson read a paper on the

TREATMENT OF PYREXIA

The writer thought the cold bath frequently repeated the most effectual means of reducing temperature in fevers, and thought that the difficulty in the way of administering it in ordinary household practice might be met by using India-rubber bathtubs The cold pack ranked next in value in his estimation, while cold affusions he thought were of very limited application Of drugs, quinine occupied the first place as an antipyretic, but it must be used in much larger doses than usual in order to obtain its full effect Recent clinical experience had shown that the fear of bad results from large doses of quinine was unfounded to a great extent With kairin, antipyrin, etc, further experience was necessary before their value could be fully determined The use of antipyrin certainly was not wholly free from danger

Drs Buckmaster and Wigginton, of the Committee on Nervous Diseases, presented papers on topics connected with *Insanity*

Dr Wigginton discussed the

RELATIONS OF MEDICAL MEN TO THE INSANE,

which he thought were possessed of a higher degree of importance than was sometimes assigned to them There were some cases of insanity which ought to have the benefit of hospital treatment at the earliest possible time, and there were others for which the hospital was productive of harm rather than good, and the physician should take time and pains to discriminate between these classes

In the debate which followed Dr Wigginton's paper, it was suggested that as the law now stood there was but little opportunity for making the full and exhaustive investigation of each case that the physician deemed advisable, and that the only way of meeting the difficulty was by the establishment of a special hospital to which all cases of alleged insanity should be sent for observation Such a hospital would relieve the physician of much embarrassment, while it would on the other hand be better for the patient and his friends

Dr Buckmaster reported a case of *Mysophobia*, and read a paper entitled

ILLUSTRIOUS INSANE

He pointed out the fact that even in their own day many of the prophets were accounted madmen, and said that were they living to day their recorded proceedings would certify them as candidates for treatment Mahomet, Joan of Arc, Martin Luther, John Bunyan, Swedenborg, the elder Booth, and many others were enumerated in his list

A Special Committee on the

RELATION OF PHYSICIANS TO THE COURTS

was appointed at the meeting of the Society in 1884, Dr F W Epley, of New Richmond, being chairman Dr Epley reported that the Committee had prepared a bill providing for the proper compensation of witnesses called to testify to matters of opinion, and had introduced it into the legislature, but that it had entirely failed to receive favorable consideration, and that there seemed no use whatever in making further efforts in that direction, as the law makers could not be brought to see that there was any difference between scientific opinion and evidence as to matters of fact

After a full discussion of the Committee's report, Dr G H Fox, of Oregon, said that if the Society would back him up he would agree to make

A TEST CASE IN THE COURTS

when next summoned on subpœna as an expert, by refusing to be sworn or to testify unless properly compensated He thought that if the profession generally would pursue this course, it would not take long to bring the courts and the legislature to a sense of the value of their knowledge

Dr McLeod also expressed his willingness to make a test case for the courts and it was resolved that a Committee be appointed with power to levy an assessment on the members of the Society for the purpose of raising a fund to pay the cost of making up a test case for the Supreme Conrt

Dr Gapen said that he had had occasion to look up the matter, and that there was thus far no precedent established and recorded in any court of the United States concerning the right of expert witnesses to compensation, and that the action of the Society in this matter would be of interest to the medical profession of the whole country

Various papers were presented from other Committees, among which were one on *New Remedies*, by Dr Stockman, one on *The Diagnostic Value of Koch's Cholera Bacillus*, by Dr Farnham, which was illustrated by microscopic preparations, one made in Koch's own laboratory, a paper on *Medical Humbugs, Regular and Others*, by Dr Berwig, an account of a case of *Compound Fracture of the Ankle*, by Dr McArthur, and one of a case of *Periostitis*, by Dr G H Fox

Dr G M Steele, of Oshkosh, was elected President for the ensuing year, and Drs S C Johnson, of Hudson, and D C Davies, of Columbus, first and second Vice-Presidents Dr J T Reeve retains the office of Secretary Drs J R Barnett, T P Russell and L G Armstrong were elected to the Committee on Ethics, and Dr N Fenn was reelected Censor for three years

About twenty new members were admitted, four of whom were ladies, this being the first occasion of the admission of female members to this Society

Courtesies were exchanged with the Provincial Medical Society of Ontario, which held its annual session at the same time, and communications were received from the State Societies of New Jersey and Nebraska and from the American Medical Association

The resident physicians of Milwaukee entertained the Society at the Plankinton House on Wednesday evening, June 3, and the Directors of the Sanitarium at Waunatosa invited a visit to that institution, placing a special train at the disposal of the Society

The city of Madison, in which the Society held its first meeting, was selected as the place for the fortieth session, which will commence on the first Tuesday of May, 1886

STATE MEDICINE

SANITARY CONVENTION AT YPSILANTI, MICHIGAN

Great interest was manifested in the Ypsilanti Sanitary Convention, which was held June 30, and July 1, 1885, under the auspices of the Michigan State Board of Health The physicians of Ypsilanti the professors of the State Normal School, and a large number of other prominent citizens of that place were in constant attendance About twenty physicians and health officers from other places were also in attendance

C L Yost, Mayor of the city, opened the convention with a brief address of welcome, in which he said that "In times past we have been honored with the presence of other assemblages for consultation upon religious, political, medical, or other interests, but this is the first time that disinterested philanthropists have come to us to discuss those great practical questions relating to the guardianship of public health" He thought that the adage "An ounce of prevention is worth a pound of cure," was the inspiring motive that brought them together Their city was more than usually blessed with conditions for good health, still they recognized the value of detailed instruction in sanitary subjects Sanitary science is in its infancy, and all attempts to further it and bring intelligent attention to its teachings should be welcomed by thinking men everywhere

Edwin Willets, President of the Michigan State Agricultural College, presided over the convention, and in his address dwelt upon the

VALUE OF HUMAN LIFE CONSIDERED FROM AN ECONOMIC STANDING POINT

as worked out by eminent statisticians A number of people who should produce $3,000 000 when in good health, could produce when not in good health only $2,000,000 Here is a loss of one-third, much of which could be saved by applying the simplest sanitary precautions It is the duty of a community to keep these human earning-machines in good condition of health or earning capacity, even from economical motives A community has the legal right to do this We want pure water and plenty of it, clean streets, cleansed sewers and drains, swamps drained, cesspools filled up, and we should not count the cost on our fingers The crowning labor of our medical science is in the warding off of disease Given by heredity a sound constitution, pure air, pure water, and nutritious food ought to guarantee to every human being, as he puts his foot on this earth, his three score years and ten, with which assurance he might plan the labors of a long life

Rev Dr Woodruff, of Ypsilanti, read a paper on

THE MORAL EFFECT OF SANITATION

He told of the importance the ancient Jewish people gave to sanitation, and in a forcible way pointed out its power in elevating man morally as well as socially and physically He thought the present attention given to sanitary matters is not temporary The reform has come to stay

PROF AUSTIN GEORGE, of the State Normal School, spoke of the

SANITARY NEEDS OF SCHOOL BUILDINGS AND GROUNDS

1 School sites should be on gravelly soil, a natural knoll, admitting thorough drainage 2 Wells should not be nearer than 100 feet to the outhouses 4 Basements should be high, with free circulation of air under ground floors School rooms should contain 250 cubic feet of air space for each child The light should come in over the left shoulder The windows should go to the ceiling, and within three-and one half feet of the floor The blackboard should be on the side of the room opposite the windows, and never have a glossy surface 4 The simplest heating and ventilating apparatus is the hot-air furnace, and for small buildings the jacketed stove The foul air outlets should be ample, and at the floor level With any system, the rooms should be frequently flushed with fresh air through windows and doors The temperature should be kept at 70° Fahr, not by teachers' sensations, but by thermometers 5 Perfect desks and benches are not yet made, they should be adjustable, to suit different sizes, and be constructed with reference to the curves of the body There should be foot-rests which could be raised or lowered until each pupil is made comfortable and able to take a healthful position Many spinal complaints and pulmonary diseases are produced by improper desks 6 Means for drying wet wraps should be provided 7 Precautions against fire should be had, especially in the heating apparatus and the chimney 8 "Inasmuch as the State educates the children, and compels their attendance in public buildings, the State should see that the children are not subjected to any preventable cause of disease"

DR. BION WHELAN, of Hillsdale, Mich, spoke on

SANITATION IN SMALL CITIES

The water supply should be guarded from contamination from cesspools and vaults If we could not have sewers, the most feasible plan for disposing of garbage is to divide the city into districts, and have it removed by licensed scavengers Sanitary science should be taught in schools The women should be taught sanitary needs, as much of sanitary work falls upon them The nature of contagious diseases, and means for their restriction should be known by all

DR J K KELLOGG, of Battle Creek, spoke of the

DISPOSAL OF SLOPS AND GARBAGE,

illustrating by use of the blackboard He pictured in a graphic way the ordinary condition of back-yards, as contrasted with front-yards He prefaced his subject proper with a brief description of bacteria and other low forms of microscopic life, and showed the relation of these to decay, no decay being possible without their intervention He showed the importance and usefulness of certain sorts, the dangerous nature of others He spoke of flies in relation to filth They are a very strong indication of the presence of filth, and consequently of germs, and it is even believed that the germs of certain diseases may be spread by them Whenever a house is full of flies, you may be certain that slops or garbage of some sort has been allowed to accumulate about the premises He stated that the air about cesspools, foul drains, and other filthy places is usually swarming with micro organisms, and he believed that even if such germs were not the direct cause of certain diseases, the continual breathing of such air predisposes thereto All sources of filth should be carefully and speedily removed from the habitation and its vicinity Garbage can be reduced to a minimum by a little attention to domestic economy Much food that becomes garbage through carelessness could be turned to good use if not neglected Even after due care, however, some refuse will remain So far as possible this should be burned That is the best method of disposal Where it is impracticable, a water-tight, covered receptacle can be used for receiving such refuse, which should be removed frequently by a paid scavenger, or otherwise Slops should not be thrown upon the ground, into open drains, or into cesspools in the yard He had known of frequent instances in which wells and cisterns were contaminated from the seepage of foul privies, drains and cesspools If slops must be poured on the ground, set off a portion of the back end of the garden, and distribute the slops on different parts of it on alternate days, giving in this way some opportunity for the soil to oxydize the organic matter Slops containing excreta from contagious diseases should be thoroughly disinfected

DR O W WIGHT, of Detroit, spoke on the

PREVENTION OF COMMUNICABLE DISEASES

He showed clearly the contagious nature of those diseases, the great and unnecessary loss of human life resulting therefrom, and how they were best restricted, citing cases from his own long experience in Milwaukee and in Detroit The main points in outbreak of a contagious disease are

1 On the part of the householder and physician (*a*) Speedy determination of the nature of the disease, (*b*) Prompt notification to Health Officer, (*c*) Cheerful acquiesence in regulations of Health Officer 2 On the part of the health department (*a*) Immediate separation of the sick from the well, as only those who are required to nurse should be allowed in the room, the sick room should be an upper chamber, (*b*) Strict quarantine of the premises, and placarding of premises, if smallpox, all exposed should be vaccinated in both arms, (*c*) Private funeral, (*d*) Thorough disinfection, after death or recovery by chlorine gas or fumes of burning sulphur, of bedding, clothing, premises, etc

Dr Wight thought that diphtheria and scarlet fever were sometimes spread by careless physicians,—criminal carelessness During four years in Detroit he had witnessed a large growth of public sentiment in favor of public health work

DR VICTOR C VAUGHAN, of Ann Arbor, next spoke on

WATER SUPPLY

Sources of water-supply are three: cisterns, surface, and subterranean. Cisterns should always be plastered outside and inside, with an excavation at least two feet larger than the reservoir, so that a brick or stone wall may be built or plastered as above. Cistern water, when boiled and filtered, is the best for use. Dr. Vaughan cited cases in Ann Arbor and Adrian in which drain water percolated into cistern water, causing malignant typhoid fever. In the discussion of surface-water, he said that we had in this country all the conditions for the development and spread of the cholera germ should it once reach our shores. Well-water is a suspicious water, because of the ease with which contamination can be carried down through the sand and gravel into the well. Subterranean water is not necessarily pure. By carefully selected illustrations he showed that contamination may be carried through the soil a very great distance by the percolation of water, the water acting as the carrying agent.

Dr. Ruth A. French, of Ypsilanti, read a paper on

MANAGEMENT OF EARTH-CLOSETS

It is a practical way out of the privy nuisance for towns too small to have sewers and a general water-supply. Earth-closets deodorize the secreta, destroy germs of contagious disease, and are necessary to invalids.

Erwin F. Smith, Esq., of Lansing, spoke on the

RELATIONS OF SEWERAGE AND WATER SUPPLY TO THE DEATH RATE IN CITIES

His general propositions were: 1. Some method of sewage disposal is a necessity of civilized life, 2. Dry earth closets, *properly cared for*, will answer for isolated dwellings and small villages, but water carriage is the only system adapted to large towns and cities, 3. The presence of typhoid and cholera is in an inverse ratio to the sewerage of a city, 4. The modern increase of diphtheria cannot be attributed to sewers, 5. The death rate from all causes falls whenever a city is thoroughly sewered, and never attains its *ante sewered* maximum, 6. Judged solely from the standpoint of pecuniary economy, the lowest of all standards, sewerage and water supply can be successfully defended against all opposition.

The statistics used in this paper are drawn from the highest authorities, American and foreign, are brought down to the close of the year 1884, and in many cases cover long periods, 10 to 40 years. They show that typhoid fever has fallen off from one-half to nine-tenths in sewered cities since they adopted sewerage, and that such cities are practically secure from the ravages of cholera. *Per contra*, in non-sewered cities the typhoid fever and the cholera mortality is as great to day as it was thirty years ago.

At the close of the convention arrangements were made for the organization of a Local Sanitary Association, the local committee of the Convention being a committee to complete this organization.

(FROM OUR OWN CORRESPONDENT.)

Deaths from Starvation and Privation—The London School of Medicine for Women—Shortening the Round Ligaments for Uterine Displacements—The Better Feeding of the People.

The usual annual return of deaths in the Metropolitan district upon which coroner's juries have returned a verdict of death from starvation or accelerated by privation shows that the number of these deaths in the year 1884, was thirty-seven, of these, eight occured in the central division of Middlesex, twenty-six in the eastern division, two in the western and one in the Greenwich division.

In the absence of Mrs. Garrett-Anderson, the Dean of the London School of Medicine for Women, Mr. A. T. Norton read the report for the past year, at the late distribution of prizes and certificates won by the pupils. This stated that the year had been one of great progress, and there had been a larger entry of pupils than in any previous year. Fifteen pupils had joined last October, and two more in the summer. Five had passed the final professional examination of the King and Queen's College of Physicians, Ireland, and four the final examination. Two had passed the M. B. examination of the University of London, and seven students who had taken their diplomas have been studying in the large hospitals in Vienna. Referring to the success of past students, the report stated that Miss Julia Cook had been appointed medical officer to the Sunnyfield Convalescent Home, and Miss Tomlinson as medical officer to the Camden Schools. The experiment that had been tried of providing female medical officers for the female clerks in government offices had worked well in Liverpool, London and Manchester. After the distribution of the prizes Professor Gladstone congratulated the school on the progress it was making year by year. It was not the time now to discuss the question whether women should or should not be allowed to become properly qualified medical officers. That battle had already been won. Addressing the students directly, he said there could not be a higher and nobler life than the one they had chosen, and their power for good amongst the families they would be brought into contact with would be inestimable. He believed a great and successful future was before that institution. Mrs. Westlake moved a vote of thanks to Professor Gladstone, which was seconded by Professor Harvey, of Calcutta, who spoke of the immense good already done and to be done by woman doctors in India.

At the last meeting of the British Gynæcological Society a most instructive and interesting paper was read by Dr. Alexander, of Liverpool, on the "Operation of Correcting some Uterine Displacements by Shortening the Round Ligaments." Dr. Alexander pointed out that the operation had been performed in most of the large continental cities, and invariably with more uniform success than generally befell any new operation. He never found any difficulty in finding and drawing out the ligaments. He made an incision upwards and outwards from the pubic spine, in the direction of the inguinal canal, for one and a half to two or three inches, according to the fatness of the subject. A considerable thickness of subcutaneous fat was then met with which must be cut through by subsequent incisions, until the pearly, glistening tendon of the external oblique muscle was reached. Midway through the fatty tissue an aponeurosis sometimes appears, so firm and smooth that it might cause the operator to think he was deep enough, but he would find no ligaments at this spot. The first stage of the operation consisted simply in cutting down upon the tendon of the external oblique muscle, until it appeared clean and shining at the bottom of the wound. The external ring was then found. The finger passed to the bottom of the wound detected the spine and the ring outside. Having isolated the external wound, and tied any little muscles, the next step was to find the end of the ligament. By everting all the structures upwards, the round ligament could be seen, generally at the lowest part, and with the white easily distinguished genital branch of the genito-crural nerve along its anterior surface and close to it. The ligament at this stage was more or less rounded in shape. It was an easily recognized flesh colored structure. When the ligament was identified, the small nerve on its surface was to be cut through without dividing any of the ligament. Then gentle traction was to be made, either by the fingers or by broad blunt-pointed forceps. Bands, holding it to neighboring structures, were cut through with scissors. As soon as it began to peel out, it was left and the opposite side begun.

The final stage of the operation consisted in placing the uterus in position by the sound, and pulling out the ligaments until they were felt to control that position. A curved threaded needle, with fine catgut, was used to stitch each ligament to both pillars of the ring, and the external abdominal ring was closed without strangulating the ligament as it lay between it. The ends of the ligaments were now cut off, and the remainder stitched into the wound by means of the sutures that close the incision. A fine drainage-tube was inserted, and the wound washed out with carbolic or other lotion before these sutures were tied. The after-treatment consisted in rest. The tubes should be removed on the second day, when the wounds were dressed. As to the dangers of the operation, the mortality was stated to be nil. Three deaths had occurred but they were due to preventable causes. The real question at issue was whether the operation fulfilled the intentions of the operator, viz.: corrected certain uterine displacements and thereby relieved the discomfort of the patient; this, of course, must depend on whether or not the symptoms were due to the displacement. To secure success the operation must be properly performed, and the after-treatment must be rational, so that no strain might be placed on the ligaments until sound union had taken place.

The first of a series of receptions to promote the movement for the better feeding of the people, was held recently at the Parke's Museum of Hygiene. It was explained to the visitors that wheat-meal bread (instead of white) oat-meal, barley, lentils, haricot beans, etc., with the addition of fresh fruit and vegetables should, for the sake of both economy and health, be much more largely used than at present.

QUADRUPLE PREGNANCY.

Dear Sir:—At 6 A.M., July 3d, I was called to see Mrs. D. R. Barnett. I found her greatly enlarged, with extreme œdema of the feet and legs. Labor had commenced four hours previously. Pains were frequent and regular, the os dilatable and a vertex presenting; the waters had not passed. After rupturing the sac labor progressed more rapidly, and about 8 o'clock a female child was born. The pains continuing, I examined again, and discovered a breech presenting, also in an unbroken sac. Shortly after rupturing this a male babe was delivered. Much to my surprise the pains continued, and after caring for the second child I examined again, and found another vertex engaged and also in its own sac. This I could not rupture in the usual manner with my finger, but had to use a pair of blunt scissors. In fifteen or twenty minutes a second female babe was safely delivered. I thought that surely this was enough, but the pains continued constant and strong. Thinking it must be the placenta, I cared for the third babe before examining. When I was ready I discovered a second breech presentation, this also in its own sac. This sac I had to rupture with the scissors on account of the toughness of the membrane. In about twenty minutes the second male or fourth child was delivered, but apparently dead and bloodless. However, after working over it for about ten minutes, respiration and circulation were well established. I delivered the placenta in fifteen or twenty minutes after the birth of the last child; it was in one piece and very large, though the union of four placentæ could be distinctly seen, with their four cords attached. The babes weighed, in the afternoon of the same day, 21½ pounds in all. The girls 5¼ pounds each, the boys 5½ pounds each. The mother and children are all well and progressing finely at the present writing; the babes being nursed on the mixed plan.

The parents are Scotch, having come to this country three years ago. They had five children previous to the late addition; all are very healthy and came single. The lady is 35 or 36 years of age, medium size, and has been robust.

Yours truly,
M. ARTHUR, M. D.

Waverly, Dakota, July 19, 1885.

RENAL CALCULI.

Dear Sir:—In the issue of the JOURNAL of June 27th there is reported a case of "Renal Calculi," which caused inflammation of the kidney, inv the neighboring structure and leading to a

WATER SUPPLY

Sources of water supply are three cisterns, surface, and subterranean Cisterns should always be plastered outside and inside, with an excavation at least two feet larger than the reservoir, so that a brick or stone wall may be built or plastered as above Cistern water, when boiled and filtered, is the best for use Dr Vaughan cited cases in Ann Arbor and Adrian in which drain water percolated into cistern water, causing malignant typhoid fever In the discussion of surface-water, he said that we had in this country all the conditions for the development and spread of the cholera germ should it once reach our shores Well water is a suspicious water, because of the ease with which contamination can be carried down through the sand and gravel into the well Subterranean water is not necessarily pure By carefully selected illustrations he showed that contamination may be carried through the soil a very great distance by the percolation of water, the water acting as the carrying agent

Dr Ruth A French, of Ypsilanti, read a paper on

MANAGEMENT OF EARTH-CLOSETS

It is a practical way out of the privy nuisance for towns too small to have sewers and a general water-supply Earth closets deodorize the secreta, destroy germs of contagious disease, and are necessary to invalids

Erwin F Smith, Esq, of Lansing, spoke on the

RELATIONS OF SEWERAGE AND WATER SUPPLY TO THE DEATH-RATE IN CITIES

His general propositions were 1 Some method of sewage disposal is a necessity of civilized life, 2 Dry earth closets, *properly cared for*, will answer for isolated dwellings and small villages, but water carriage is the only system adapted to large towns and cities, 3 The presence of typhoid and cholera is in an inverse ratio to the sewerage of a city, 4 The modern increase of diphtheria cannot be attributed to sewers, 5 The death rate from all causes falls whenever a city is thoroughly sewered, and never attains its *ante sewered* maximum, 6 Judged solely from the standpoint of pecuniary economy, the lowest of all standards, sewerage and water supply can be successfully defended against all opposition

The statistics used in this paper are drawn from the highest authorities, American and foreign, are brought down to the close of the year 1884, and in many cases cover long periods, 10 to 40 years They show that typhoid fever has fallen off from one-half to nine tenths in sewered cities since they adopted sewerage, and that such cities are practically secure from the ravages of cholera *Per contra*, in non-sewered cities the typhoid fever and the cholera mortality is as great to day as it was thirty years ago

At the close of the convention arrangements were made for the organization of a Local Sanitary Association, the local committee of the Convention being a committee to complete this organization

RENAL CALCULI

Dear Sir —In the issue of the Journal of June 27th there is reported a case of "Renal Calculi," which caused inflammation of the kidney, involving the neighboring structure and leading to a fatal termination This case, though somewhat unique, resembles in some respects a case that occurred some time since in my practice

At the autopsy of the body of Mr S the left kidney was contracted and completely disorganized, being merely a sac containing a large irregular calculus with débris The weight of the calculus was about 200 grains The right kidney was contracted and granular The capsule of the left kidney had ruptured on the anterior aspect, where there were several cysts There was no disease of the liver, gall-bladder, heart, nor other organs The body of the patient was well nourished and contained a great amount of fat The cause of death was severe shock

When I was called at 1 P M, June 27, 1883, the patient, though suffering great pain, was in a collapsed condition Under the influence of a gr ¼ of sulphate of morphia, administered hypodermically, the patient soon became easy and fell asleep The pulse improved and warmth to the hands and feet soon returned, but as the morphia wore off towards morning, the patient again became collapsed, though not so severely as at first Hypodermic injections of whiskey and enemata of beef tea and strong coffee were administered, but the patient only partially rallied and sank again and died at 4 P M, on the 29th

The patient had been for years troubled with rheumatoid disease, the hands, feet and knees being often greatly swollen The frequent attacks of pain were always very severe, and could only be relieved by subcutaneous injections of morphia Although seen by many eminent physicians, the diagnosis was uncertain Gall stones as the cause of these attacks had been more than once suggested, but none could ever be found in the fæces He was often affected with jaundice No renal calculi at any time were found in the urine The pain was more frequently complained of as being located in the centre of the abdomen and about the region of the pylorus and to the left of the umbilicus The calculus was composed of oxalate and phosphate of lime, similar to those referred to above The length of the painful attacks was often different, sometimes lasting only a few days and at other times for weeks, and then the patient would rally and resume his official duties as constable and collector Careful and repeated examination of the urine gave only negative results The patient for several years had been under my care The autopsy was conducted by Dr A F Holt, one of the State Medical Examiners

Very respectfully,

AUGUSTUS P CLARKE, M D

Cambridge, Mass, July 8, 1885

A LOST INSTRUMENT

Dear Sir —I forwarded a sample instrument and description of same, a "new combined trocar and aspirating needle," to the Chairman of the Section on Surgery for presentation at the meeting held at New Orleans, 1885 The instrument was presented (the Chairman informs me), but never returned to him I trust that you will publish this card, so that the individual in whose possession the instrument now is, may know where it of right belongs I trust the present possessor will forward the instrument to me so that I may use the same as a sample by which the manufacturer may produce another, if they will oblige me this much I promise them a return of the instrument, which I had constructed at an expense of about eight dollars

ASSOCIATION ITEMS

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with FIVE DOLLARS, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly JOURNAL OF THE ASSOCIATION will be forwarded for one year

VAGINAL HYSTERECTOMY FOR CANCER[1]

BY A REEVES JACKSON, M D,
OF CHICAGO ILL

The only fair method of judging the value of any surgical procedure is to consider its results If these be such as to lessen suffering and prolong life it is useful, and hence proper If, on the contrary, it fail to effect either of these ends, it is useless If, further, it be found after sufficient trial to be destructive of life, it is worse than useless—it is injurious, and ought to be abandoned Judgment should not be rendered prematurely, nor upon insufficient data Neither should it be based upon theoretical grounds, facts only can be the foundation of an honest opinion

My purpose in this paper is to apply these principles to the extirpation of the cancerous uterus, with the view of determining what our attitude ought to be in reference to this operation The abdominal, or Freund's method having, on account of its frightful mortality, been abandoned, or used only in exceptional cases in which removal through the vagina is impracticable, my remarks will have reference wholly to the vaginal operation

What, then, has vaginal hysterectomy done to deserve our favorable consideration? About three and a half years ago, Hegar and Kaltenbach published a table showing the results of the operation from the date of its revival by Hennig, in 1876, down to the time of the report It comprised 29 cases, with a mortality of 27 6 per cent In 1883, Sanger compiled a table which included 133 cases, of which 38, or 28 6 per cent died At the annual meeting of the American Gynecological Society, held in Chicago, September, 1884, Dr Paul F Munde stated that he had collected 256 cases, with a mortality of only 24 6 per cent

Everybody knows that all tables of this character are imperfect, because incomplete They include only the cases which have been published, or which may possibly have come to the personal knowledge of the compiler It is equally well understood that the successful cases are far more likely to be published than the others For example, in my own city (Chicago) the uterus has been removed by the vaginal method four times One of the patients recovered, and three died The first was published, the others were not The single successful case goes into the record showing a recovery rate of 100 per cent, if its three companions were also considered, the rate would be 25 per cent Facts of this kind serve to explain a remarkable discrepancy which is apparent when the results of operation as shown by tables of cases gathered from miscellaneous sources, and assumed to be correct, are compared with those of individual operators whose cases are all given to the world To illustrate Dr Engelmann, of St Louis, in a letter published in the *Weekly Medical Review*, September 1, 1883, stated that down to August 5, Martin had operated by the vagina 50 times, losing one half At the meeting of the British Medical Association, in 1883, Prof Schroder, of Berlin, who had operated in 23 cases, admitted that his mortality was 34 per cent Ohlshausen, also, in a letter which was read on the same occasion by Sir Spencer Wells, stated that he had operated, or attempted to operate in 28 cases, and his results were equally bad with those of Schroder The combined number of operations performed by these three men alone was 101—that is, two fifths of the entire number comprised in Dr Mundé's table. The mortality in these 101 cases was 38 6 per cent. If Dr Munde's data be correct, the operators in the remaining 155 cases were fortunate in having a rate of mortality so preposterously low as to excite wonder Thus, if the mortality in 256 cases was 24 6 (Mundé), the number of fatal cases was 63 Of these, as we have seen, 39 were included in the 101 cases of Martin, Schroder and Ohlshausen This leaves 24 other fatal cases to be furnished by the remaining 155, and shows a mortality of 15 4 per cent !

It seems only just to the gentlemen I have named, to suppose that if all the cases operated upon were published their results would not appear so relatively bad Indeed, from their well-known skill and experience in pelvic and abdominal surgery we should expect from their work the very best possible success, as would doubtless appear if a good deal of the truth in relation to the subject were not suppressed. Figures will not lie if they have a fair chance

In view of the tendency to publish successful cases, and the aversion and frequent failure to publish those which are unsuccessful, the conviction is forced upon me that the mortality of vaginal uterine extirpation is not very greatly less than the published mortality of Freund's method, which, in the same manner, was made to appear less than it really was

---

[1] Read in the Section on Obstetrics and Gynecology at the Thirty Sixth Annual Meeting of the American Medical Association

But, accepting only the published cases, and basing a calculation upon this latest table[1] of 256 cases, with 63 deaths, what is its significance as regards the saving or destruction of life?

While it is impossible to know exactly how many years these 63 women who died would in the aggregate have lived, if permitted, it has been estimated that cancer of the cervix, if left to itself, kills in about seventeen months from the time of the appearance of the distinctive symptoms, and that of the corpus in two and a half years. If we grant that in all these cases the disease affected the cervix, and that the average length of life would be only seventeen months, then the years of life sacrificed would be nearly one hundred. If, in some of them, the disease affected the body of the uterus, as it doubtless did, the aggregate amount of life destroyed would be still greater. And if the unreported fatal cases were added, it would be much greater still.

What is there to offset this? Has a single patient been radically cured, and a life otherwise doomed saved by the operation? There may have been, but I do not know that such a claim has yet been made. Schroder[2] has said, "If only one out of twenty be radically cured, this ought to be considered a good result, and as a consolation for many cases treated unsuccessfully." Most surgeons, I fancy, would feel very inadequately consoled by saving one patient and losing nineteen. But here even the one seems lacking. It has been urged that the prognosis of the operation will probably be better when its technical details become more perfect. Unquestionably, it is reasonable to hope that such may be the case, and certainly it is greatly to be desired. But, so far, the history of the operation in this respect is not encouraging. In 1881 Schroder issued a report of eight operations performed by him, with seven recoveries and only one death. After two years' further experience and fifteen additional cases, his percentage of mortality was nearly three times greater.

But, admitting that the operation may by-and-by become less dangerous, what then? Its dangerous character is by no means the gravest charge against it. Indeed, taken alone, it would hardly be a valid one. A far more serious objection to it is that it is not beneficial when it fails to kill. What does it for those who survive? What do they gain? Are they spared the manifold suffering incident to the disease? Are their lives prolonged? Many patients pass from observation after their recovery, and nothing is known of their subsequent history. Probably, however, this does not differ from that of those who continue under notice, and in these recurrence takes place in all, sooner or later. So absolutely is this true that, in any case offering an apparent exception to the statement, the accuracy of the diagnosis may fairly be doubted. Dr Linkenfeldt, assistant at the clinic at Strasbourg, says that in all cases of total removal of the uterus for cancer performed by Freund relapse followed quickly. In a single instance it happened after two and a-half years. In seven cases given by Sanger the average time of recurrence was 4.2 months. Schroder says: "As to the success obtained by vaginal extirpation, I must admit that it is not yet to be called satisfactory, especially as far as the question of recurrence is concerned." And again, "In a great number of my patients I have seen recurrence, in some cases after two or three years. Other cases have withdrawn from my observation, and only very few have remained until to-day quite without recurrence." All candid testimony corroborates this of Schroder.

And now I ask: When recurring symptoms manifest themselves after the temporary diminution or cessation procured by operation, are they in any manner or degree beneficially modified? Are the hæmorrhages less profuse or less exhausting? Is the leucorrhœa less offensive or less irritating? Is the pain less poignant? Does the cachexia kill less certainly? To all of which the answer must come, assuredly not.

Are lives prolonged by the operation? Observations embracing the complete history of those who have recovered from the operation show that they die, on an average, in a shorter time than if let alone.[1] And this is what we might reasonably expect, since so severe an operation is likely to exert a depressing influence upon a person already laboring under an exhausting and deadly disease. Then, if the operation sacrifices many lives and does not save any, *if it only postpones or interrupts suffering and does not avert or lessen it*, what can be said in its favor? Only this beggarly plea can be urged: that it may in the future not destroy so many, and may possibly even save a life. But should this great and certain evil continue on the mere possibility—the almost baseless hope—that a trifle of good *may* follow? Is this a fair administration of the trust put in us by those who impliedly rely upon our honesty as well as upon our skill?

But, it may be asked, shall no effort be made to save the unfortunate subjects of this dread disease? Unquestionably, it is not only proper, but obligatory upon us to make any and every legitimate endeavor to stay its progress, to mitigate its evils, to avert the threatened death. Such attempts have been made, and are constantly making. But of all the methods employed for these purposes the one which has furnished the worst results, and which has the most utterly failed, is the extirpation of the uterus. Not only is this true of the operation when it is compared with other methods of treatment, but, as already shown, it kills more rapidly than does the disease when allowed to pursue its natural course.

Advocates of the operation are already beginning to place limitations—in theory, at least—upon its employment. Schroder thinks total extirpation ought to be restricted to two classes of cases, namely: 1. Those in which the cancer affects only the body of the uterus, and, 2. Those in which it is limited to the cervical mucous membrane. Dr

---

[1] A more recent table was compiled by Dr. W. A. Duncan for the Obstetrical Society of London, and published in the Lancet for January 31, 1885. It included 276 cases, with 197 recoveries and 79 deaths—mortality 28.6.

[2] British Medical Journal, September 15, 1883.

[1] Sänger (Archiv f. Gynäk., xxxi, 1) states that in six cases observed by him the average time which elapsed between the operation and death was 14.1 months.

Munde, in the paper to which I have referred, agrees with this, but further states that there should be a sufficiently capacious vagina to permit the ready exposure of the cervix and vaginal vault, and also that the condition of the general system should be sufficiently vigorous to permit the patient to endure the shock of the operation.

These restrictions are eminently proper, so far as they go. They are based upon the fact, admitted by all, that if the disease has at all involved the peri uterine structures it cannot be wholly removed, and recurrence is certain. The precept is admirable, but the practice does not and cannot correspond with it. The determination of the essential question involved is attended with insuperable difficulty. In the present state of our art there is no method by which the extent of cancerous involvement in a given case can possibly be known. The microscope may sometimes, perhaps generally, tell us of the existence of the disease, but, during life, at least, is certainly incapable of defining its limits. Isolated cancer cells, conveyed by lymphatics and other avenues, are frequently found scattered through the connective and glandular tissues at a considerable distance from the original growth. These outlying areas of affected structure cannot be submitted to microscopical examination prior to operation, the only time when the knowledge obtainable by it could be available for the purpose of deciding the propriety or possibility of radical removal.

Schroder[1] has stated his belief in the feasibility of distinguishing by the touch with perfect certainty very small infiltrations such as occur principally along the lymphatic vessels. I greatly doubt the possibility of making an accurate diagnosis by this means, and the unreliability of the information furnished by it is clearly shown in the rapid and numerous recurrences of the disease after the distinguished gentleman's own operations. When cancer is limited to the cervical mucous lining it is rarely detected, perhaps never. And if it be so limited, the removal of the entire organ is surely not indicated. The excision of a conical portion, including the external os uteri, and extending beyond the internal os, should be sufficient to remove all the diseased tissue. But I repeat, the disease is not discovered here. At least 90 per cent of the uterine extirpations have been done for cancer of the cervix, and from the greater frequency, and more easy recognition of the disease in this locality, such will doubtless continue to be the ratio. And here, even the men whose opinions I have cited, and who can hardly be called conservative, regard total extirpation as improper. And for very good reason. When cancer affects the cervix uteri its extension is not upward, towards the body, but circumferential, and supra-vaginal amputation, with a mortality about one fourth that of total removal, does all that the latter can do.

This, then, practically reduces the field of the operation to cancer of the uterine body. We know less of the disease in this locality than in that of the cervix. As compared with cervical cancer it is much rarer, although of greater frequency than was formerly supposed. Likewise, it is of much longer duration than cervical cancer, and, while confined to the uterine tissues, it is attended by comparatively slight pain. The progress of the disease is by way of the Fallopian tubes and the network of lymphatics which surround the organ on all sides. The difficulties of diagnosis are great, and not likely to be settled until too late to operate. After pain has become a prominent symptom the surrounding tissues are probably involved, and any operation which does not include the tubes and broad ligaments would be incomplete.

Why should a highly dangerous method be chosen in dealing with uterine cancer when others less perilous and equally efficient can be employed? The various operations by the curette, scissors, caustics, cautery, etc., as employed by Sims, Wells, Byrne, Barnes, Van de Warker, Baker, and others, have given results, both immediate and remote, far superior to those of extirpation. In the *Lancet*, for Aug. 2, 1884, there was published an abstract of a valuable report by Pawlik, of 136 cases of cancer of the cervix treated by the galvanic cautery in the first gynecological clinic at Vienna, the observations extending back to 1861. Of the entire number nine died shortly after operation—a mortality of only 6.6 per cent. Not only in regard to the death-rate, but in every other particular the results were incomparably better than those following the erroneously styled radical method. Indeed, all the minor operative measures to which I have referred, and which are commonly called "palliative," appear to be more radical as regards permanency of cure than total extirpation, and, since their mortality is only about one-fifth of the latter, they should for every proper reason be preferred.

I beg to offer the following conclusions:

1. Any operation for cancer which does not completely remove the disease will be followed by recurrence.

2. During life, the diagnosis of the extent of cancerous disease originating in any part of the uterus, is at present impossible; hence, no operative procedure can afford a guarantee of complete removal.

3. In view of this necessary doubt, no operation is justifiable which greatly endangers life, provided other and safer methods of treatment are available.

4. Vaginal hysterectomy has sacrificed the lives of more than one third of those who have been subjected to it—the mortality of the operation when done by those of greatest skill and experience being over 36 per cent.

5. Other methods of treatment, attended by not more than one sixth to one fourth the mortality of vaginal extirpation, are equally as efficient in ameliorating the symptoms and retarding the progress of the disease; and they have been followed by as good or better ultimate results. Hence, they should be preferred.

6. Vaginal hysterectomy does not avert or lessen suffering; it destroys, and does not save, life. It is, therefore, not a useful but an injurious operation, and being such, it is unjustifiable, and ought to be abandoned.

DO WE FIND FROM MICRO-ORGANISMS IN ENCLOSED CAVITIES A HITHERTO UNSUSPECTED DANGER TO SURGICAL LESIONS?[1]

BY HENRY O MARCY, M D,
OF BOSTON MASS

This brief communication is suggestive, and must take the form of a query, since the observations are too limited to allow conclusions except in possibility The following clinical histories are at least interesting and instructive

Case 1 —In the summer of 1883, Mrs L , aged about 30, consulted me for pain in one limb which had given trouble since the birth of her only child, 18 months before, Her general health was excellent Only a few days after visit, I was informed of her sudden death She stepped heavily from a horse-car and felt something, as she expressed it, "give away" in her abdomen Death followed in forty hours

The autopsy showed a general peritonitis with an effusion of several quarts of a milky fluid The left ovary presented a partly collapsed cyst, size of a pigeon's egg, from a small opening in which had escaped a very little dark colored semi fluid material The cyst was evidently old, with a thick, degenerated, friable wall I preserved and carefully examined the free abdominal fluid and the contents also of the cyst The abdominal fluid shewed abundant exudation cells and fine granules, amidst which were swimming innumerable large bacilli, in morphological characteristics, not unlike those of anthrax Abundance of similar bacilli were found in the contents of the cyst These were cultivated in bulbs and reproduced as a pure culture, unmixed with other bacterial forms There can be little doubt the cause of death was due to infection from this source

Case 2 —Miss W , aged 40, a patient in my private hospital, with large compound ovarian cyst of rapid growth with thin walls General health fair Careful examination of urine gave no evidence of renal disease

Operation was performed with strict antiseptic care Removal attended with difficulty, on account of adhesions and one or two cysts were unavoidably ruptured with partial escape of contents into abdominal cavity The peritoneal cavity was very carefully sponged with 1-1000 bichloride solution Operation followed by severe shock, but the patient rallied very well

Second day—urine free and normal, when the quantity rapidly diminished almost to suppression and became albuminous Temperature rose to 101°, and it was supposed that septicæmia had supervened

Third day—patient worse, cysts in urine, albumen abundant Temperature, however, scarcely exceeded 100° Death occurred 76 hours after operation

Autopsy showed absence of peritonitis Exudative repair had supervened in the stumps of both ovaries, but there was about two ounces of a reddish serum in the retro-uterine pouch This fluid was swimming with micrococci and colonies of the same were found in the kidney The surprise to me was, whence the infection, since the patient had not developed a general peritonitis, and care considered trustworthy to avoid infection had been scrupulously carried out during the operation The cyst had fortunately been preserved, immersed in a solution of 1-1000 bi chl of mercury, awaiting careful examination Fluid from an unruptured cyst contained active micrococci, undistinguishable from those found in the body after death These were cultivated in bulbs and reproduced in masses as well as in pairs Did death ensue from micrococcal poisoning from the cystic fluid escaping into the peritoneal cavity at the time of the operation?

Case 3 —F L , aged four and one half years, seen in consultation with Dr Z B Adams, of Framingham This case has been reported by him in the *Boston Medical and Surgical Journal*, for November 20th, 1884 Patient seized on the 17th of May with fever and diarrhœa Temp 104 Pulse 120 Evening temperature 105° Pulse 140 Stools slimy and containing mucus Continued very ill for four weeks, when I saw her At that time she was greatly emaciated, abdomen distended, walls tense, veins enlarged over surface Temp 103° Pulse 140 Extreme weakness Aspirated over a pint of creamy fluid, which, microscopically examined, contained abundance of micrococci, pus corpuscles often disintegrated, fine granules and fine oil globules Cultivated in bulbs, a pure culture actively reproducing in pairs only

Ten days later I assisted Dr Adams in making an exploratory incision, the slight gain which followed the aspiration having been lost and the child appearing *in extremis* About two quarts of fluid, similar in appearance to that aspirated, escaped, the abdominal cavity was washed out with a solution of mercuric-bichloride and the opening closed without drainage Temperature fell to normal and the patient rapidly improved

The twelfth day afterwards, however, there was a spontaneous opening, preceded by fever and suffering, and a discharge of considerable purulent fluid Thereafter the patient made an uninterrupted recovery and has continued well, is at present growing rapidly Whence came the micro organisms?

Are ovarian cysts to be considered no longer closed sacs? How can bacteria enter the unopened abdominal cavity? Have we in cystic fluid a hitherto unsuspected surgical danger ? I have consulted a number of our best observers, none of whom have discovered micro organisms in cystic abdominal fluid It may now be accepted that micrococci are always present in acute abscesses, and are probably to be considered causal But here we must provide soil as well as seed, and certain local changes in nutrition probably precede, devitalization from injury, prolonged irritation, as a foreign body, modifications of blood supply, etc Many experiments go to show that micrococci may be introduced into the circulation and be eliminated by the kidney without causing a serious injury to a healthy animal This is not difficult to explain, or accept as possible, since, to obtain development, a lodgment must be effected and retention at rest Stasis in the blood current in or about a local injury, as a bruise, or during the early stages of lactation in the turgid state of the mammary gland, so-called cold or inflammation gives readily the local condition favoring lodgment, and thus planted, the out-cropping is speedy and effective Although the presence and development of micrococci in the free fluid of the abdominal cavity and in ovarian cysts might thus be explained, it would be difficult to show how a bacillus of the size and virulence described in Case 1 found lodgment and retention in an old ovarian cyst, even if we consider as possible or even probable that they might enter by the way of the uterus and Fallopian tube

---

[1] Read in the Section on Surgery and Anatomy at the Thirty Sixth Annual Meeting of the American Medical Association

In reply to a letter addressed to our distinguished friend, Dr Drysdale, whose experience in the microscopic study of ovarian fluid is perhaps greater than that of any other observer, he informs me that he has not detected micro organisms in ovarian fluid However, without special means of examination, micrococci might be overlooked, and earlier, bacilli even would have been considered as accidental, confounded with bacteria termo and regarded as entirely unimportant It must, however, be considered exceptional that micro organisms are to be found in ovarian cysts, since observations of accidental rupture of large cysts without serious result are not infrequent Dr Hunter, in the *N Y Medical Journal*, April 4, 1885, in a very valuable paper entitled "Fifty Cases of Abdominal Section," reports as Case VIII, the rupture of the sac and disappearance of the tumor, a month later, when the refilled cyst was removed, the point of rupture, firmly closed, could be distinctly seen, and a quantity of the discharged ovarian fluid yet remained in the abdominal cavity No disturbance followed the rupture and no peritonitis supervened Dr Hunter justly observes that "this case illustrates the fact that the fluid contained in an ovarian cyst is not necessarily irritating to the peritonæum When this case was reported to the Obstetrical Society, several others were cited in which the peritonæum had tolerated the presence of ovarian fluid I have several times seen the abdominal cavity bathed in fluid from ovarian cysts ruptured during operations, without any bad consequences afterward "

In accord with a number of our best modern observers, I would relegate the so called "idiopathic peritonitis," with amaurosis and many another learned phrase, to the terra incognita of ignorance, and hope the last case cited above, although novel, may be suggestive of a possible surgical helpfulness, where at least medical treatment is confessedly unavailing

DISCUSSION

Dr W A Bird, of Illinois, stated that Dr Martin, of Berlin, was the first who proposed opening the abdominal cavity in cases of peritonitis The cases of Dr Marcy reminded him of an interesting case he had in 1882, which he saw at the time with Dr Beck The patient was a negro woman with a cystic abdominal tumor in the right side, he diagnosticated cyst of right ovary, and aspirated three pints of fluid from it A few days after she had what resembled malarial fever, the doctor, thinking that it might be best to remove the tumor, subjected her to the operation, after she had rallied from that attack He opened the abdominal cavity but found no trace of tumor The whole peritoneum was studded with millet seed looking objects which he took for tubercles After making a thorough examination he closed the cavity, and in doing this found great difficulty in bringing the cut edges together The woman made a perfect recovery The only diagnosis Dr Bird can suggest for this case is hydatid cyst, which was absorbed after aspiration

The speaker said that he had performed ovariotomy ten times, and had lost five cases, in none of the unfavorable cases had the tumor weighed less than thirty pounds He had operated for herniotomy twenty-six times with only three deaths, ten times he had cut into the intestines and none of those cases had died, he had once cut away ten inches of the gut, and the case had terminated favorably He thought that the trouble in all those cases of abdominal section was that they were operated on too late, he always operated soon and with his patient in good condition He had opened the abdomen seventy-six times and had lost eleven cases

Dr Hurtz thought Dr Bird's case was not a case of ovarian cyst, but one of hydronephrosis Dr Bird had probably aspirated the dilated ureter

Dr Bird said that he had, at the time of the operation, inspected the kidney and had found it normal, that it could not have been a case of hydronephrosis

Dr Beck, of Illinois, thought from what he had heard that the case he was going to mention was not out of place Some time ago a lady had come to consult him, with what he diagnosed a large simple cyst of the ovary, there were no complications, the uterus was of normal size He advised her to be operated on, and she had returned home to make necessary preparations for the operation One week after her departure he was telegraphed for by the lady's husband, who stated that his wife was dying He repaired immediately to the place and found the lady suffering with intense pain, the cyst was gone, and the swelling of the abdomen was more diffuse, the patient was almost collapsed She rallied, however, and in a short time got well, the tumor having completely disappeared This was evidently a case of rupture of the cyst, and afterwards absorption of the effused fluid Upon inquiring into the cause of the rupture, Dr Beck learned that on the evening before he was sent for, the husband had attempted to have intercourse with his wife, and that a too sudden pressure of the man's body on the woman's distended abdomen had caused the cyst to give way, this rupture had been accompanied with immediate intense pain

LACERATION OF THE FEMALE PERINEUM

BY H V SWERINGEN, A M , M D ,

OF FORT WAYNE, IND

At a meeting of the Indiana State Medical Society, in May, 1882, I read a very short paper on the above subject, in which I cited five cases in support of the position therein assumed, that the deferred operation was preferable to the immediate, and that neither was as frequently required as the profession generally supposed. In consequence of the very unpopular stand I took upon this subject, I was quite surprised, though agreeably, at the favor with which my paper was received by the Society. I must mention, however, one notable exception, a leading gynecologist of Indianapolis, and a prominent member of the Society, who was absent at the time it was read. This gentleman, a year later, while reading a paper on "Laceration of the Cervix Uteri," took occasion to refer to my paper of the previous year, and to express his regret that he was not present at its reading.

The paper was sent for publication to the *American Journal of Obstetrics*. Dr. Paul F. Mundé, the editor, wrote me that "while he thought the paper was worthy of publication and would publish it, he hoped the doctrine it promulgated would never be adopted by the profession, inasmuch as he did not think it sound."

In this paper I wrote as follows: "I am disposed to favor the deferred operation. The fact as to whether or not the immediate operation may not be considered one of the fashions of the healing art, can never be determined until nature has been given a fair opportunity to manifest her power in effecting spontaneous cures of ruptured perinei. I commenced the preparation of this report a week ago to-day, subject to the interruptions common to the practitioner. A mere glance at the literature of the subject was taken, Goodell and Thomas having been hastily consulted. But I am here to relate my *own* experience, and not that of the excellent authorities referred to, however difficult it may be to divest myself of that gregarious spirit which is disposed to follow in the track pointed out by a few leaders." (Here follow the cases, to which, for our present purpose, it will be unnecessary to refer.) I then proceeded as follows: "If natural, unaided parturition, which we must regard as a healthy, physiological function, is not infrequently followed by pathological and necrological results, the immediate closure of a ruptured perineum by sutures tends to favor these results by reason of the sources of infection their puncta create. The fact that in many instances these results do not follow this operative procedure, does not in the least detract from the soundness of the position here taken. An open, unsutured, non-uniting but cleanly rupture, is certainly not so likely to become infectious as a closed, sutured, ununiting and therefore uncleanly laceration, leaving out of the question the foci of infection produced by the the sutures alone. On this point Dr. Goodell says: 'The fears entertained by some physicians of septicæmia are purely hypothetical, for, although the suture tracks form, in one sense, new foci of infection, yet they close up a raw surface, whose area is vastly larger than theirs.'

"But there is a certain proportion of cases in which these raw surfaces, though sutured, do *not* unite, and in which the suture tracks therefore increase largely the area of exposed absorbing surface, and, hence, increase largely the risk of danger. It is in the interest of this certain proportion of cases that this subject should be discussed, for if it can be shown that one death in a thousand cases results from the immediate operation, and not one in ten thousand from the deferred, and that nature alone, if let alone, would be more frequently successful in effecting a cure, our rule of action is made plain. Parturition under the most favorable circumstances is attended with great risk, and if we can well postpone an operation which would have the least tendency to increase this risk, it is our duty so to do. If, then, it could be established beyond a reasonable doubt that, all things being equal, in all cases of ruptured perinei in which art succeeds in effecting an immediate union, *nature would likewise prove successful*, the immediate operation should never be attempted."

Such was my language in 1882, upon the occasion to which I have already referred, and the lapse of time since that date has not only wrought no change in, but abundantly strengthened my views upon this important, practical question. I am the more emboldened in the stand I then took, by having recently seen an article in the *New York Medical Record*, of June 20, 1885, upon the same subject, by Dr. Frank Hastings Hamilton, of New York. He says:

"*Immediate or Primary Operation.*—I cannot agree with some modern gynecologists, that it is better in such cases to proceed at once to close the rent by sutures, and for several reasons, some of which have already been anticipated. The parts have suffered such a degree of stretching and contusion as to render the occurrence of inflammatory reaction, if not of sloughing almost inevitable, the lochial discharges will make it impossible to keep the parts clean, the operation itself inflicts a severe injury when the condition of the patient is already critical from other causes, and finally, because under judicious management the rent frequently becomes partially and sufficiently closed spontaneously.

"If spontaneous closure of any portion of the rent takes place under these circumstances, it is probably not usually effected by the direct contact and immediate adhesion of the lacerated surfaces. The conditions are all unfavorable to this occurrence. Lacerated and contused wounds seldom unite by first intention, and the torn edges are too narrow and irregular to be placed and maintained in exact apposition, even with the aid of sutures. The surgeon encounters sufficient difficulty in securing this result even when, at a later day and under much more favorable circumstances, and after an extensive denudation of the surfaces, he attempts the closure by the aid of sutures. It is much more probable that the union occurs in these cases by the secondary process of granulation, the cicatrization and restoration commencing at the angle of the wound where the laceration terminated, and extending thence in the direction of the vaginal orifice. This is what happens usually in the case of a lateral incision, made for the purpose of enlarging the orifice of the mouth after certain plastic operations upon the lips, and which, without great care on the part of the surgeon, is certain to defeat his operation. Indeed, I have generally found it impossible to prevent the union of the parts thus divided, except by covering one of the raw surfaces with the mucous membrane dissected from the inside of the lips

"While, therefore, the accoucheur may be advised to maintain actual contact of the raw surfaces by position, in the remote hope that some adhesion may occur, there is not in this possible chance of small results a justification for operative surgical interference The parts should certainly not be needlessly or forcibly drawn asunder, but they may be carefully exposed to view each day, and made clean by gentle ablution, and the urine should be drawn by a flexible catheter as often as may be required for the relief of the patient, to whom nothing is more distressing than the contact of the urine with the raw surface of the wound

"In further support of the opinion above given, that an immediate operation is not in most cases, if ever, advisable, it must be explained more fully that, if it were possible to secure union by adhesion at this early period, the operation must be made within a few hours at most Hewitt ('Diseases of Women,' Sims' Amer ed, vol 1, p 462), who advises the early operation 'when the rent is at all considerable,' says 'the primary operation should be performed within one hour from birth, while the surfaces are still raw and bleeding' 'It is of very little use in inserting sutures when the labor has been over some hours, union rarely then occurs' This statement is doubtless correct, and my experience in a great variety of plastic operations compels me to doubt whether the operation will be any more successful if made within an hour The reasons for this opinion have already been assigned But we may properly ask Mr Hewitt what is to be done with that very considerable number of cases in which the expulsion of the placenta is delayed beyond an hour? Shall the rent be closed before it is expelled, at the risk of the sutures being torn out by its subsequent passage? Or is the accoucheur again to interfere with the course of nature, and, with more or less violence, as may become necessary, remove the placenta without reference to the present general condition of the patient or of the uterine contractions?

"From any point of view it comes to this, that it is proposed to make an operation, by no means trivial in its character, requiring, according to Hewson, two or three 'rather deep silver-wire sutures,' not to speak of the subsequent special management of the bowels required, and the removal of the sutures, and which operation at the best is very liable to fail, and which may subsequently, in case no operation is made, be found to have been unnecessary, if it becomes necessary, can be made more thoroughly and successfully at a later period—it is proposed, I say, to make the operation under every surgical disadvantage, and when the patient, prostrated and trembling from the results of a severe labor, is in the worst possible condition, both mentally and physically, to endure the shock of an operation, or even its announcement Nothing but the most urgent, imperative necessity can justify the operation under these circumstances, and this necessity has not been shown to exist It is proper, also, to add that not every accoucheur is competent to make an operation of this nature, and experts in this department of surgery can seldom be obtained within the hour assigned by Hewitt as the limit of its probable success This may not constitute an argument against the primary operation, but it may be pleasant to the accoucheur, who has omitted to perform it, to believe that happily it was not necessary or advisable At this early period, also, it is often difficult for an expert even to form anything like a definite opinion as to the actual extent of the lesion A rent, which at first seems to be an inch or two in length on account of the distended condition of the perineum, will, after contraction, a few hours later, be found to be not more than a quarter or half an inch"

Such is the language of Frank Hastings Hamilton, M D, L L D, written three years after my own paper on the same subject was read at Indianapolis My reasons for quoting his views *in extenso* can, therefore, be readily appreciated

Dr Harvey, in his paper on "Laceration of the Cervix Uteri" already noticed, and which was read a year subsequent to that of my own, spoke as follows "I regret that I could not possibly be present last year, when a paper was read on laceration of the female perineum If put together immediately after parturition, the parts will reunite and the perineum will be perfect before the patient leaves her bed Failure will not occur in one case out of a hundred if the operation is timely and properly performed I hold that it is the duty of the physician, instead of going off and saying 'I never had a case of lacerated perineum occur in my practice,' and instead of ignoring such cases and leaving women to suffer in after years, for fear he may be censured for not having so conducted the labor as to prevent the laceration, he should admit its presence, and explain that it is an accident of labor that may happen in the hands of the most skilful and experienced obstetrician

"Scanzoni states that he has prevented many cases from perineal laceration by making several incisions around the parts, probably, however, no obstetrician is sufficiently expert to prevent laceration, and our writers on gynecology and our teachers in medical colleges and societies, instead of teaching students and practitioners how they can always prevent laceration of the perineum, should say 'Gentlemen, you can not always prevent laceration of the perineum, it will happen in certain cases in spite of all your efforts to prevent it, all that you can do is to give chloroform and allow plenty of time to relax the parts' But when it does occur let us admit it, and explain to patients and friends that it is not an uncommon accident of labor, that the physician is always looking out for it and is there to restore it, and that if properly and immediately treated, the patient will be well in a week The physician who says that it will not heal by first intention, or that he don't get good union upon immediate restoration, has either not put it up properly, or does not know what he is talking about I may say here, and in no spirit of boasting, but only to impress upon you the necessity of immediate operation for your own defense and the relief of suffering women, that I have not had in a large practice in this line, but two failures, and these are not to be properly regarded as failures, there was in each case a little fistulous opening, which was readily cured by the after application of nitric acid"

Now, when views so diametrically opposed, upon a question of such practical importance, are presented to the young practitioner, it will be difficult for him to decide which course he had better pursue The rule is to follow the great majority That might, however, does not always make right, or that a doctrine that is quite generally accepted is not, therefore, necessarily a sound one, is nowhere more clearly illustrated than in the history of medicine The difference of opinion among physicians can frequently be very satisfactorily explained For example, a Philadelphia or a Chicago specialist—a gynæcologist, it may be—deals largely with what may be called "exceptional cases," *i e*, cases that prove decidedly exceptional to the general rule governing their etiology, pathology, history or treatment They may be cases of lacerated perinei sent to him by physicians from all parts of the country, whose treatment as a *general* rule, in the great *majority* of similar cases, has been eminently successful without resorting to operative procedure, cleanliness, and that apposition of the parts which is secured by the maintenance of a proper position of the patient, being all that was necessary Now, the specialist, being in almost constant contact with such "exceptional cases," no longer regards them as such, but looks upon them as representatives of the *rule* rather than of its exceptions, and hence forms and expresses his opinions accordingly, wholly unmindful of the vast number of cases that have escaped the results for which he is consulted

My experience in the field of obstetrics, though slight in comparison with that of many of my brethren, inclines me to the belief that, since the time of mother Eve, that woman never lived whose perineum was not more or less lacerated in giving birth to her first child at the full period of utero gestation I say "more or less" lacerated, by which I mean from the slightest tear or rent of the fourchette to the most complete rupture, including a division of the recto vaginal septum

In glancing over my obstetric record for the last two years, I find that in a little over two hundred cases, I have delivered by forceps in forty one, more than one fourth of whom, of the latter, were under the charge of other physicians, who did not fail to "wait upon nature" until the very last moment, and, in two instances, the babes were dead before sending for assistance

In each of those forceps deliveries, all of which were in cases of primiparæ, there was laceration, more or less extensive, principally "less," in several it seemed, upon first examination, sufficiently large to suggest the propriety of sutures, but subsequent investigation disclosed the fact that the rent was not so large as at first supposed In no case, in my opinion, was the rent any more extensive than it would have been had the forceps been unemployed, indeed, I have seen cases of far greater rupture in which there had been no instrumental interference In no case did I introduce a single suture, having resorted in every instance to simple cleanliness, and to keeping the patient confined to a lateral decubitus, with the knees together In a few cases I resorted to catheterism for several days, and to sprinkling a little iodoform over and around the rupture They all recovered promptly In one case only were sutures employed, not by myself or with my consent, but by the physician who had the case in charge, and who sent for me to deliver the same I did not see her subsequent to her delivery She did not get along as well as any one of the other cases, in the great majority of whom, however, the rent was inconsiderable, a mere rupture of the fourchette being the extent of laceration Whether or not the introduction of the sutures was the cause of her tardy recovery I shall not assume the province of determining Of one thing I am certain, however—that in the case cited in the paper I read before the State society the rupture was so extensive that for several days it was utterly impossible for her to retain her fæces, and yet the union of the divided parts was speedy and perfect without the use of a single suture

Thomas, in his valuable work on "Diseases of Women," page 129, writes "Even when the rupture has been complete, it has been asserted that spontaneous cure has taken place, but such reports need confirmation Peu once affirmed that he had seen a woman thus injured, and who passed her fæces involuntarily, entirely recover De la Motte declares that thirty years afterwards he met and examined Péu's patient in Normandy, and found that no recovery had occurred"

There are, doubtless, by reason of peculiar constitutional conditions, not a few cases in which neither the immediate, deferred, nor any other operation will be successful One would naturally suppose it difficult, by the immediate operation, to secure that perfect natural co aptation or apposition of the divided parts that we do, for instance, in suturing an incised or lacerated wound of the scalp The condition of the tissues involved in both cases is by no means the same, in the former case they are not in that state of quiescence which marks the condition of the latter, and hence the presence in them of sutures no doubt interferes with their gradual assumption of, or restoration to, the natural state, alters the original relative position of the parts, and thus gives rise to irritation, inflammation, suppuration, etc, all of which increases the dangers of the puerperal condition

The cases of rapid recovery *with* sutures are more than overbalanced by the cases of rapid recovery *without* them, and the cases of non-union *without* sutures are more than counterbalanced by the cases of non union *with* sutures In both of the latter groups of cases some general constitutional defect, scrofulous or what not, may lie at the bottom of and account for the failure of union by the first or second intent.

In view, then, of the foregoing, and of the fact that the lying-in woman has been compared to gunpowder, requiring but the spark to set it ablaze, who will—who can—question the propriety of allowing the puerperal condition to pass away before attempting the restoration of the lacerated perineum, especially when, in nine cases out of ten, if the proper precautions are taken, nature will render unnecessary *any* interference, either immediate or remote.

So far as the prophylaxis of ruptured perinei is concerned, I have no confidence in any. If in any sense I am a believer in the doctrine of predestination, it is in the matter of lacerated perinei in cases of primiparæ. If a perineum will not give sufficient to allow of the passage of the child's head, it will tear enough for the purpose, and that is all there is about it. As Josh Billings once said: "When a man begins to go down hill everything seems greased for the occasion," so, when a large head with sufficient *vis a tergo* or *vis a fronte* distends an obstinate, unwilling perineum, everything seems favorable for a rupture, and something must yield.

HOSPITAL REPORTS.

MERCY HOSPITAL, CHICAGO.

SERVICE OF EDMUND ANDREWS, M.D., LL.D., AND E. WYLLYS ANDREWS, A.M., M.D., SURGEONS IN CHARGE.

Case 1.—Diagnosis of Cancer by Chemical Tests Applied to the Blood.—In the *Allgemeine Wiener medizinische Zeitung*, of February 21, 1885, Dr. Ernst Freund claims to be able to detect carcinoma by the presence of sugar or glycogen in the blood, and sarcoma by finding in that fluid the presence of peptone. It is claimed that his method has stood victoriously the test of application to about one hundred different patients. If this method shall prove reasonably trustworthy it will be of immense importance in the diagnosis of tumors, especially of those located internally. Our first case is one of carcinoma. Six months ago we removed a moderate sized epithelioma of the lower lip. The wound healed and remained so to this day. No enlarged glands could be found below the jaw at the time, but now the patient returns to us with the whole upper part of the neck studded with cancers, two of which are in a state of fetid ulceration.

Dr. Frank T. Andrews, temporarily acting as Assistant Surgeon to the Clinic, took the investigation in hand, and commenced tests on different patients, but being called out of the city, committed the matter to Professor J. H. Long, of the Chair of Chemistry in the Chicago Medical College. Prof. Long, after a careful examination of a specimen of the blood by precipitating the albuminoids and then applying Fehling's test, reports sugar present, thus confirming Dr. Freund's statement.

Case 2.—Testing the Blood for Peptone in Sarcoma.—Freund asserts that in sarcoma the blood always contains peptone. Patient No. 21 appeared at the clinic with a large tumor deeply seated above the clavicle. It adhered to the transverse processes of the cervical vertebræ, and lay for three inches close against the internal jugular vein. From the fact that the tumor originated where no epithelial surface exists, and that in spite of its advanced condition no glands were infected, I inferred that it was a sarcoma. The microscopic examination confirmed the conclusion, and showed it to be of the spindle-celled variety. A specimen of the blood was sent to Prof. John H. Long, Professor of Chemistry in the Chicago Medical College, who first precipitated the albuminoids, and then applied the biuret test, which showed the presence of an abundance of peptone.

Remarks.—These are the only two cases of tumor which we have yet subjected to Freund's tests, but it is significant that they confirm his discovery in the most striking manner. We shall continue the investigation, and if Prof. Long's future analyses establish the truth of the discovery, it will be a very important step in surgical progress. In that case, malignant tumors can be diagnosticated in interior cavities and the question of an operation decided on an intelligent basis, and even in external tumors, a trustworthy method of determining whether they are or are not malignant will be of the highest importance.

Case 3.—Laparotomy for Gunshot Wound of the Abdomen.—Some months ago we reported two cases of gunshot wound of the abdomen which recovered easily without any operation. The first wound was made by a 22 calibre bullet which entered on the linea alba between the umbilicus and the xiphoid cartilage, traversing directly backwards. The stomach was empty. Considerable shock ensued, but no vomiting. The patient was treated by opiates and starvation. On the tenth day he passed the bullet per anum. He recovered without a sign of peritonitis.

The second case had a 38 calibre bullet shot completely through the body on nearly the same line as the previous one. Laparotomy was proposed to him, but he refused it. His stomach had no food in it at the time of the shot, but he had taken considerable beer. As he rejected the operation, he was placed on starvation and opiates, and recovered without a bad symptom.

The present patient received a 38 calibre shot which entered through the border of the cartilages of the ribs upward and to the left of the umbilicus, the bullet apparently passing close to the anterior border of the left lobe of the liver and directly towards the stomach near its greater extremity. The projectile went entirely through the body, passing out of the back at a point opposite, but two inches lower than the place of entry, and on the same side. The patient was visited by Dr. Webb and another well educated physician, who both testify that he vomited blood in considerable quantity, and suffered a moderately severe shock. He appeared at the clinic fifteen hours after the injury. So far as could be learned the stomach contained no food at the time of receiving the wound, but as he was said to drink about fifteen glasses of beer daily, some of that *life* giving fluid was doubtless present. On his arrival there was a slight elevation of temperature, and pressure detected a diffused tenderness of the abdomen, extending down to the iliac region on the right side. The pain, however, was moderate, and the decubitus was not that of decided peritonitis, as he showed no desire to draw up the knees

On consideration, it was judged best to examine the viscera by laparotomy Adopting all the usual antiseptic precautions except the spray, an incision was made along the linea alba between the xiphoid cartilage and the umbilicus The inner orifice of the track of the bullet was found on the interior surface of the cartilages of the ribs, close to the edge of the left lobe of the liver, but not wounding the latter Considerable bloody serum was sponged out, but there were no clots, and nothing like the contents of the stomach or of the intestines could be found On drawing the left end of the stomach forwards as far as it would come without violence, we failed to discover any perforation, though there were portions which could not be thoroughly searched The stomach was slightly distended with flatus and liquid, but none of it escaped into the abdomen on making gentle pressure If the organ was perforated, it was obviously by a valve shaped wound, which prevented leakage The incision was antiseptically closed and dressed, and the patient treated by starvation and opiates Immediately after the operation he vomited freely, throwing up mucus, water and bile but no blood It is now the sixth day after the injury, and the patient has entirely recovered from his slight early appearances of peritonitis, but he is fully under the influence of delirium tremens, due probably to his enormous potations of beer, since his acquaintances assert that he drank no distilled liquors

It is clear that the first two patients suffered nothing from the omission of laparotomy, and it is not clear that the third derived any benefit from it True, there was removed some bloody serum, but blood which has not been exposed to the septic germs of the atmosphere by laparotomy is often absorbed without trouble My observations lead me to think that pistol shots may often penetrate the rather thick walls of the stomach without allowing any escape of its contents, while the same sized bullet traversing the intestines, which are exceedingly thin, will instantly let out the gases and other materials within them In military practice I personally saw no recoveries from the penetrating abdominal wounds made by the great army bullets, yet even military cases are not so desperate as one would think from the size of the projectiles "The Medical and Surgical History of the War of the Rebellion" tabulates 79 cases of penetrating shot wounds of the stomach, of which 24 per cent recovered without operation, while of 653 shot wounds opening the thin walled intestines only 11 per cent recovered, showing the great difference in behavior between wounds of the two classes of viscera At that period laparotomy was scarcely heard of Billings collected nine military cases of shot wounds of the intestines which were operated on, of these five died and four survived Even this was better than the let-alone policy, but at the present time a much greater success could be achieved

The facts point to the following conclusions

1 Shot wounds of the stomach are less dangerous than those of the intestines

2 The causes of death in abdominal wounds are mainly hæmorrhage, shock, and peritonitis from effusion of the contents of the viscera

3 In the majority of cases, the danger will be greatly diminished by laparotomy, generally performed at the linea alba

4 The first incision may be small, to establish the diagnosis, and if hæmorrhage or visceral effusion is found, the opening may be enlarged to enable one to tie vessels, to sew up the perforations, or to excise ruined segments, and to clean out the effusions The moderate exploratory incision is not of itself very dangerous, if properly performed, but if it show escape of the contents of the intestines or stomach into the peritoneal cavity, it offers the only reasonable chance of saving the life

Case 4 —Ligature of the Vertebral Artery for Epilepsy —I formerly reported two cases of desperate epilepsy greatly benefited by ligature of a vertebral artery between the atlas and the axis Mr W Alexander, of Liverpool Workhouse Hospital, reports 21 cases operated on by him, of which three were cured, three failed, and all the rest were benefited None died (*Brain*, Vol V)

The present patient is an adult male, under the skilful treatment of Dr Cooper, of Batavia The fits recurred from twelve to fifteen times a week, and the mind was giving way At Dr Cooper's request I operated on him, selecting the left vertebral The case showed a remarkable tendency to hæmorrhage, especially from enlarged venous trunks, which oozed and gushed so obstinately that they rendered the operation very slow and tedious When the artery was tied, there was pallor, shock, and an external strabismus to be observed in the eyes, as also happened in one of the cases previously reported The wound was dressed antiseptically and the patient placed in bed At the end of a week he left for home, not a single paroxysm having occurred after the operation during a period in which he usually had twelve or fifteen It is of course too early to judge of final results, but I have strong hopes of decided benefit from the effort

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

The Respiratory Centre —Nitschmann (*Archiv f d gesammte Physiologie*, Bd xxxv, S 558) admits, with Langendorff, the existence of spinal nerve centres presiding over the function of respiration These spinal centres may be divided longitudinally without causing any change in the respiratory movements, but on condition that the division is exactly in the median line But if the instrument deviates to the slightest extent to one side, the respiratory muscles of the side are paralysed, and the respiration becomes unilateral This holds good of sections made above the fourth cervical vertebra

If the medulla and calamus scriptorius be divided longitudinally, respiration continues normally, the muscles of the right and left sides contracting simultaneously. The respiratory reflexes following irritation of the sciatic are strictly bilateral, the two halves of the diaphragm contracting at the same time. On the contrary, the reflexes originating in the pnuemogastric, the trifacial or the nerves of the brachial plexus act unequally on the respiratory muscles of the two sides; respiration becomes unequal.

After section of the medulla alone, irritation of the brachial nerves does not cause asymmetry of the respiratory reflexes. Section of the cervical portion of the cord alone is also insufficient to cause asymmetry of the reflexes.—*Revue des Sciences Medicales*, July, 1885.

MEDICINE

Cocaine in Affections of the Upper Respiratory Passages.—Dr. J. Strahan, in a short article on this subject, says: The fact that Jellinek has produced complete anæsthesia of the larynx by the application of cocaine, points to a vast field of usefulness for that drug, not hitherto explored. To secure anæsthesia of the larynx, epiglottis, palate, and pharynx, must prove an invaluable boon to the profession and the patient, in the immediate future. Even the action of carbolic lotion or lozenge in throat-affections, as an anæsthetic, is by no means to be despised; so that we can easily imagine the comfort, relief of pain, and even avoidance of danger to life in cases of spasm of the glottis, likely to result from the use of cocaine. It has been used with perfect success in operative procedures about the larynx, but has not yet been tried for either diphtheria or croup. It is obvious what a boon the addition of cocaine applications would be to any plan of treatment. It could be applied either by ordinary swabbing with a four per cent. solution, or by insufflation with the dry powder; or the solution could be sprayed when we wished to reach far down. Even if the applications have to be made as often as every half-hour, for a little, the trouble would be as nothing compared with the ease and safety of the patient. In case of necessity, the nurse could apply it perfectly well in any form, if taught. The addition of a couple of drops of chloroform (a solvent of cocaine), to the ounce, would prevent the formation of fungus in the solution, as it does in the case of solutions of atropia, morphia, strychnia, tartarated antimony, and indeed all solutions usually spoiled by fungi. This would conduce to economy, as the solution without any preservative soon spoils, and is then liable to excite acute inflammation in mucous membranes instead of curing it. Of course the chloroform must be dissolved in the alkaloidal solution, by agitation in a bottle not more than three quarters full. This amount of chloroform causes no irritation, even in the eye, as I constantly use preserved solution of atropia, without causing the slightest pain.

We have now evidence that a four per cent. solution of cocaine painted on the nasal mucous membrane, besides causing anæsthesia, contracts the capillaries, drives out the blood, and causes a membrane swollen and red to become shrunken and pale. In coryza, even where the nares are obstructed by swelling, a strip of lint, soaked in the solution and pushed into the anterior nares, speedily removes the swelling, permits the passage of the breath, and, repeated once or twice, even permanently cures the disease. From these considerations, it seems to me that cocaine is destined to become an indispensable aid in all acute inflammatory diseases of the upper respiratory passages. In laryngitis, croup, diphtheria, scald of the larynx, simple or reflex spasm of the glottis, and even in chronic laryngeal affections, life often depends on the absence of fits of spasm; and the only remedy, when it occurs often enough or severely enough to threaten life, is tracheotomy. If cocaine, by inducing complete anæsthesia of the parts, prevents these spasms even in part, it will be an invaluable addition to the treatment of these diseases. We have some evidence that it will do so, from the fact that the imperfect means on which we have hitherto had to rely for anæsthetising the larynx, pharynx, etc.—namely, bromides and chloral—do very markedly diminish the tendency to spasm of the glottis in croup, for instance. For that reason among others, I am of opinion that a combination of bromide of potassium and hydrate of chloral constitutes the very best treatment for croup—at least, so far as systemic remedies go. The bromide diminishes the number and intensity of the laryngeal spasms. The chloral, in addition, acts as perhaps the most powerful antiphlogistic we have in such cases; it greatly reduces arterial blood-pressure, diminishes body-temperature, and acts as a powerful germicide, both generally and locally. The local use of cocaine, and the constant inhalation of some efficient antiseptic vapor, such as that of eucalyptus oil, or of turpentine and tar, in addition to the internal treatment described, and with proper attention to alimentation, would seem to me to be an almost perfect therapeutic plan for diphtheria, croup, and many other diseases of the respiratory passages.—*British Medical Journal*, June 13, 1885.

Treatment of Cholera During the Algid Period.—Dr. Georges Rigoletti attributes the principal symptoms of the algid period of cholera, such as lowering of the temperature of the exterior of the body, cyanosis, change of countenance, inextinguishable thirst, difficulty of respiration, epigastric constriction, hiccough, vomiting, muscular cramp, prostration, general collapse, and paralysis of the heart, to a lack of the normal proportion of water in the blood. Two indications correspond to the symptomatology:

1. To restore to the tissues their normal water, and to the blood its normal serum, in order that it may perform its functions.
2. To excite the nervous force and to stimulate the heart. To fulfil these indications Dr. Rigoletti proposes the hot bath, containing ammonia and wood ashes.

The bath is prepared with water of a temperature ranging from 100.4° F. to 104° F., about one quart of aqua ammonia and a sufficient quantity of wood ashes. The duration of the bath is from fifteen to twenty five minutes, and it may be renewed in the same day, and for many days in succession, according to the case. To avoid the ammoniacal vapors, the patient is so covered as to prevent their reaching the head. The patient, on being removed from the bath, is covered with warm blankets, which favor and maintain reaction. Frictions with camphorated alcohol are also to be practised, and aromatic infusion of chamomile and spirits are to be administered. If the reaction come on too violently, it is to be moderated by ordinary measures. The efficacy of the bath is more prompt when the algid state is least advanced. The method was used in 1884 with much success in the epidemic at Naples, and the official report as to its value is as follows:

1. The hot alkaline bath administered at the beginning of the algid period stimulates the peripheral circulation and increases the power of reaction.
2. The nervous forces are strengthened; the patient is so much relieved that many times during the day he requests the bath; the constriction of the epigastrium diminishes and disappears.
3. The pulse, often imperceptible, is gradually strengthened; the features become more natural, and the face even sometimes becomes flushed. Anuria almost always ceases in the bath.
4. Diarrhœa continues, but the vomiting and hiccough disappear with the administration of the bath.
5. The ammoniacal vapors excite cough and interfere with respiration, and for this reason it is necessary to protect the patient from them. However, the effect of the vapors is beneficial in that they increase the power of the voice, and render it less rough and more intelligible. In conclusion, the hot alkaline bath is a powerful therapeutic agent in the algid period of cholera, and its effects are most constant.

Dr. Rigoletti concludes his paper by stating that reaction, under treatment with the bath, is always *prompt*, occurring within twenty-five minutes; *complete*, as shown by the disappearance of all algid symptoms; and *constant*, having never failed in twenty-three cases in which the algid condition was treated by its use. He considers it the remedy, *par excellence*, for the period of the disease, and much superior to the intra-venous injections of salt water proposed by Dr. Hayem and to the subcutaneous alkaline injections of hot water suggested by Prof. Cantani.—*Journal de Médecine de Paris*, May 10, 1885. *Am. Journ. Med. Sciences*, July, 1885.

The Hygienic and Climatic Treatment of Pulmonary Phthisis.—This year's Croonian Lectures were delivered before the Royal College of Physicians in London by Dr. Hermann Weber. By pulmonary phthisis the author means a chronic disease of the lungs, with consolidation beginning almost always at the apex, having a tendency to caseation, softening, and the formation of cavities, or of fibrous changes; all the changes may occur in the same individual at the same time in different parts of the lungs, or may follow one another at different periods of the disease. These changes are mostly found associated with the tubercle bacillus, discovered by Koch, and are intimately connected with a state of mal-nutrition of the whole organism, especially the cells and tissue of the lungs. There is no doubt that the bacillus is intimately connected with phthisis, but the exact relations appear to require further elucidation, as to why it thrives in some persons and not in others; or why it thrives in a person at one time and not at another. It is known that the range of temperature within which the bacillus of tubercle can grow is much more restricted than in the case of some of the other bacilli. Its growth entirely ceases below about 82° F., and above 107° F.; it thrives best at about 97° F. to 100° F. A further point against the spread of the tubercle bacillus out of the animal body is that it does not form spores in the air. When there is any catarrh of the mucous membrane of the bronchi, and especially of the smaller divisions, and when the expiration is imperfectly performed, the bacillus finds a favorable opportunity for its development. The lecturer then shows that many cases of phthisis are certainly curable; and in the *post-mortem* room many instances are familiar to every one of old phthisical cavities having healed. With reference to treatment, it is impossible to restrict ourselves to that of the developed disease, and to pass over the preventive treatment. In many cases this is the only chance, for, when the disease is once established, in some constitutions it runs a rapid course. The poor have far less hope of recovery than the rich; and, contrary to what is the case in many diseases, existing hospitals cannot put the poor on a par with the rich in the question of the treatment of phthisis. That phthisis is capable of being transmitted from patient to patient is an accepted fact, in the author's mind, and numerous precautions are laid down with reference to the manner in which persons suffering with the disease should behave when living among those either with or without hereditary tendencies. The second lecture commences with the curative treatment of phthisis. This subject is divided under five headings: 1. Diet; 2. Air and ventilation; 3. Exercise; 4. Management of skin, clothing, etc.; 5. Climate. Food should be taken in small quantities and often, and the appetite should be humored as much as possible; milk is the most important article. Fresh air, good ventilation, and healthy exercise without fatigue, are essential. With regard to climate, the most essential feature is the purity of the air from floating matter. A soothing climate is not so good as a tonic one; it should allow the patient to remain in the open air, and at the same time enable him to take exercise and to gain an appetite. The author speaks very strongly on the use of alcohol by phthisical patients, and is convinced that in health alcohol is rarely necessary, but that in phthisis, especially in the febrile stage, it is of the greatest use, as long as the kidneys are sound. The third lecture deals with the effects of climate, and commences with the remarks on the beneficial results produced by the dry cold of the Alps in winter on phthisical patients. Altitude climates are recommended in hereditary and acquired tendency to phthisis, but in advanced or complicated cases no benefit is derived from them. After mentioning several health resorts, the author concludes by remarking that the climate of several places in Great Britain is good for the prevention of the disease, but not for developed cases The health resorts on the southern coast lack the necessary arrangements required to render them suitable for consumptives, and Dr Weber urges the medical profession to use their influence in securing the erection of well-arranged houses with suitable balconies, verandas, covered walks, seats, etc, and with shelters from cold winds, so that those who cannot afford a journey abroad may reap the full benefit derivable from home climate —*London Medical Record*, June 15, 1885

Reduced Iron in the Treatment of Anæmia —Dr John W Martin, of Sheffield, England, states in the *Medical Press and Circular* of December 3d, 1884, that for some time he has been using reduced iron in the treatment of anæmia with the greatest success, and thinks that it is one of the most powerful remedies which we possess in restoring the condition of the blood in all anæmic states of the system He has employed it chiefly in chlorosis, amenorrhœa, chorea and enlargement of the spleen following intermittent fever, and states that with the exception of those cases in which the impoverishment of the blood has been due to nursing, the cases in which he has found this form of iron most serviceable are those of young girls and women of chlorotic tendencies, and in women who have reached the change of life, in whom, beyond an unexplainable failure in the powers of nutrition, no organic disease is discernible According to him, administration of this drug has been followed by symptoms of improvement within 48 hours, and the patients have steadily progressed to convalescence without change of treatment When a tendency to constipation is present this may be best overcome by the use of the following mixture

℞ Magnesii sulph ʒ iiss
Magnesii carb ℥ ij
Tr nucis vom, mxl
Sp amm aromat,
Tr cardamomi aa ℥ ij
Aq menth pip, ad ℥ viij
M ℥ i bis die

The iron is usually given in the form of a pill, of which the ingredients and the strength of their dosage may be varied as circumstances may demand The following prescription is that which he has found most serviceable

℞ Ferri redact grs iiss
Ext nucis vom, gr ⅛
Ext quassiæ, q s

M ft pil no xij

S —One to be taken three times a day at meal times

Cocaine in Hay Fever —Dr Wm S Paget says, in the *British Medical Journal*, of June 27, in regard to the use of cocaine in hay fever To alleviate the itching and burning of the eyelids (always an early and prominent symptom) I use a two per cent solution, and apply it, by means of a camel's hair brush or the tip of the finger, to the margins of the lids, dabbing a little into the eye at the inner canthus If too much be not used, there is no inconvenience from dilatation of the pupil, the remedy is thus applied as often as the symptoms present themselves For the relief of the nasal symptoms I have used a four per cent solution, introducing a couple of drops into each nostril by means of an eye-dropper, holding the head well back, and sniffing it up It is well to have only a small quantity (for example ʒj) of these solutions made up at once, and the little bottles are conveniently carried about for use at any time The use of goggles to protect the eyes from glare and dust is also most important, and they should be worn regularly, whenever the light is bright, from the commencement of the disease until the susceptibility has passed away

Treatment of Erythema Nodosum —Mr W E Buck says that the raised patches of erythema nodosum which are generally found over the tibiæ, are sometimes very painful, and are usually slow in receding He has acted in accordance with the belief that this disease is due to inflammation of the lymphatic vessels and spaces, and that it is more closely allied to erysipelas than to any other disease, he has, therefore, treated it antiseptically with sulphurous acid In three cases, treated in this manner, he has met with marked success, the pain being relieved, and the patches rapidly subsiding

His method is to soak lint in a mixture of equal parts of fresh sulphurous acid of the *British Pharmacopæia* and hot water, heated to boiling-point, the lint is then wrung out, and placed over the patches When it cools, it is changed for another piece —*British Medical Journal*, June 27, 1885

SURGERY

Treatment by Section of Hydrocele by the Antiseptic Method—Mr Edward Bellamy, in discussing the treatment by section of hydrocele by the antiseptic method, says The few remarks I make are based upon the results of a considerable number of cases I have treated, both in hospital and in private practice, in the early and later stages of hydrocele, by which latter I mean those which have been repeatedly tapped, and in most cases injected It is hardly necessary to take up space by instancing the individual cases It is certainly time that the old-fashioned method of tapping, and the supposed radical cure by continuous injection, was done away with, as painful, dilatory, and generally useless I claim no originality whatever in this treatment I desire to call the attention of practitioners to the fact that they should invariably adopt the method of free incision with strict antiseptic precautions, and I cannot understand why it is not more universally carried out Every surgeon knows of the method, but, as far as I see, contents himself with adhering to the usual proceedings There is no danger in it An anæsthetic can be given if necessary, the healing is rapid, the cure almost certain, if not absolutely so The operation is as follows The diagnosis, of course, being established, the scrotum should be shaved, and (if the surgeon thinks necessary) the spray used, the tumor is firmly grasped, so as to render the parts as tense as possible. A clean sweep through all the scrotal tissues is then made with the bistoury, from the cord to the base, and the fluid escapes. Every bleeding vessel, however small, must be twisted or tied most scrupulously, and the interior of the sac carefully examined for any vessel which may have been wounded or have given way. The cavity should then, not too tensely, be stuffed with lint soaked in 1 in 40 carbolised oil or gauze, and the upper part of the edges of the wound stitched together, including all tissues—I do not see any advantage in stitching the cut edges of the sac to the sides of the wound—a small tag of the contents being left out of the most dependent part on the contingency of drainage, a pad of salicylic wool placed over all, and the scrotum supported by a cushion between the thighs. In a couple of days the parts may be dressed (under spray, if thought desirable), and the contents of the sac withdrawn. As a rule, considerable contraction of the walls of the sac will have set in, but it is advisable still to introduce the antiseptic material so long as any appreciable cavity exists, and this is generally for about a week in very favorable cases, when it will be found impossible to pass anything into it and merely the lips of the original wound are left to close. Tubal drainage is, I venture to think, unnecessary. I have not yet met with any untoward constitutional symptoms by adopting this method, which is equally applicable to encysted hydrocele of the cord.—*Lancet*, July 4, 1885; *Med News*, Aug 1, 1885.

OBSTETRICS AND GYNÆCOLOGY

SYPHILIS AND TABES.—PROFESSOR EULENBURG has recently published an article on the relation between syphilis and locomotor ataxia (*Virchow's Archiv*, January, 1885). The following are his views: 1. There is an absolute and relatively somewhat large percentage of tabetic patients who have suffered from syphilis; the number of these is considerably larger than was generally admitted until within the last few years. 2. The exact relation of syphilis to tabes is uncertain. Probably in most cases syphilis acts only as a debilitating predisposing cause, like many other agencies—such as heredity, mental affections etc., but perhaps in some instances syphilis is the direct cause of tabes. 3. At any rate, syphilis can hardly be considered to be the most frequent and most important cause of tabes. 4. The cases of tabes which have been preceded by syphilis present no constant and characteristic symptoms, nor any peculiarity in their course, by which they can be distinguished from other (non syphilitic) cases. 5. As regards prognosis and treatment, also, there is no clear and characteristic distinction between the two classes of cases. Those with syphilitic antecedents may in certain circumstances improve, perhaps even recover, either with or without specific treatment, while, as a rule, such treatment is either of no avail or only attended by temporary benefit. 6. The investigation of the etiology and pathogeny of tabes in relation to syphilis, which has been prominent of late years, has not yet afforded any definite solution of the question; nor, according to the experience of the author, can the discussion be said to have yet led to any permanent result as regards the best treatment of tabes.—*Medical Record*, July 4, 1885.

DISEASES OF THE PLACENTA AND CORD CAUSED BY SYPHILIS.—DR SAXINGER (Tubingen, 1884), has published the results of his studies in this affection, with the following conclusions:

1. There exists a placental syphilis, which, in a fair proportion of cases, is recognizable on macroscopic examination.

2. Placental syphilis generally accompanies fœtal syphilis. It is also found in maternal syphilis with a healthy child.

3. The placenta may be diseased in an isolated lobe and throughout its density, or solely in its fœtal portion, or its maternal portion.

a. If the mother has been infected by the fecundating coitus, with the fœtal syphilis, the placenta is found to be more or less diseased throughout. Ordinarily the umbilical vessels themselves are diseased.

b. If the mother is not infected generally, besides the fœtal syphilis, only the fœtal placenta and the cord are diseased. Nevertheless, the morbid process may extend to the maternal placenta, and infect the mother by intra uterine repercussion.

c. If the mother has been infected some little time before conception, if the mother has been fecundated by a healthy man before the outbreak of general symptoms, and if she has undergone treatment during pregnancy, a healthy child may be born to her. Here the maternal portion of the placenta is generally the only one diseased.

d. If the mother has been infected some considerable time before the fecundating coitus, ordinarily it is the placenta alone which is diseased. Under the influence of the progress of the morbid process, the fœtal placenta and the whole of the placenta may be involved in turn, and the fœtus participate in the infection, if indeed, from the disturbance of the circulation, it is not destroyed.

e. If the mother is fecundated by a healthy man, and if she is not infected until later, in spite of the immunity of the fœtus, the placenta is always diseased, however slightly. When the mother is syphilitic, the placenta does not escape, unless the mother be infected at a period very near to her time of delivery.

4. It is not proved positively that a woman can be infected by the passage of a syphilitic child through the genital organs, nor that a child can be infected during delivery.

5. Experience shows that children conceived during the first years of acquired syphilis, or badly treated syphilis of the parents, die during intra-uterine life, or are born non-viable. A mercurial treatment which is well directed may interrupt this transmission at all periods, or maintain a condition that is latent for years. If syphilis remains so latent in an organ, it is possible, after appropriate mercurial treatment, to see healthy children born, and later syphilitic children.—*Archives de Tocologie*, June, 1885.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events, or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

THE TREATMENT OF PHTHISIS BY CLIMATES OF LOW ALTITUDE WITH MODERATE ATMOSPHERIC PRESSURE.

In a previous editorial article we endeavored to show that Jaccoud is of the firm conviction that "from a therapeutic point of view the fundamental indication" for treatment of tuberculosis "should be drawn from the atmospheric pressure rather than from the temperature, and that the climates with slight and those with a moderate degree of atmospheric pressure should be specially separated. The climates belonging to the first group are all severe in winter, but differ notably from each other in atmospheric pressure, which diminishes, as the height of the places varies from 1,650 feet, as in the more northern latitudes, to more than 4,900 feet." In the second group he places health resorts ranging in height from the level of the sea to 1,300 feet above. In these places the atmospheric pressure is moderate, "while the temperature is cool, temperate or warm in winter, hot or scorching in summer."

The effect of high climates he regards as more distinctly curative than that of low climates, which is passive or at the most but protective. In the utilization of resorts of the second group he deplores the habit of varying the residence with the change of seasons, and advocates a fixed abode in whatever locality is found to suit individual peculiarities. Care should also be taken that the accommodations be comfortable and hygienic. Of all low stations Madeira fulfils best the indications required for prolonged residence. Places by the river at the eastern extremity of Lake of Geneva, various cities above, Méran in the Tyrol, Lugano in Switzerland, and the localities immediately surrounding, are likewise more or less satisfactory. It would seem that Pisa by the side of the Apennines, Pau near the valley of the Pyrenees, the Riviera on the shore of the Mediterranean, are also admirably suited to a fixed abode, but for several reasons residence there can not be prolonged beyond the close of spring. While recognizing the importance of a fixed residence in a suitable climate, an infringement of this rule is less deleterious in places of the second group than in those of high altitudes. Hence, if individual conditions require a sojourn for the winter in a southern latitude, as in Egypt, Algiers or Sicily, a return to a temperate climate will have to be made for the summer. But such a return must be cautiously effected, the invalid waiting until the changeable weather of April and May is past. Most reprehensible is the plan of sending a patient from residence on the plains during the winter to the mountains for the summer. Local conditions important to the invalid's welfare are: that the place of abode be in the outskirts of the town where the atmosphere is uncontaminated, that the chambers be airy and well ventilated, the water closets, bath-rooms, wash-stands, bed clothing, etc., thoroughly disinfected; that there be ample accommodations for out door life, even in rainy weather; that not only excellent medical attention can be secured, but that appliances for aero-therapeutic and hydropathic treatment be at hand; that there be an abundant supply of fresh milk, and that the food be of the best quality. This last consideration makes the Canary Islands and Morocco unsuitable.

As previously stated, the effect of climates of the second group is solely preservative, not curative or prophylactic; hence, inferior to that of considerable altitude. Like that of elevated climates it is twofold. The local effect is to lessen irritability and consequently irritation of the bronchial mucous membranes, while the general or constitutional benefit is due to life in the open air together with plenty of sunshine even in the winter. In order to secure this two fold benefit, certain climatic conditions are requisite, as well as those of environment and hygiene already considered. These are, uniformity of temperature, of hygrometic conditions, freedom from winds, and comparative dryness of the atmosphere. Daily oscillations of the thermometer of more than nine degrees are deleterious, and accordingly a temperature ranging between 40° F. and 50° F. is preferrable to one with daily extremes of 60° F. and 75° F. Marked hygrometric variations subjects the consumptive to much discomfort, if not danger. On the other hand, too great dryness of the atmosphere favors so rapid an evaporation of the fluids of the body, both through the skin and lungs, as to produce irritation of the bronchial mucous membrane Hence, Jaccoud is of the opinion that the hygrometric status should be ranged between 70° and 80° This statement refers particularly, however, to temperate or hot climates, since the degree of humidity that can be well borne depends upon the degree of the temperature Freedom from severe winds is also of importance, since they not only expose the invalid to the danger of becoming unexpectedly chilled, but create dust which is a direct irritant to the respiratory passages

The necessity of selecting a resort whose climatic conditions will conduce to a local improvement of the diseased organs is not the only consideration, the effect upon the general health must be taken into account as well "If the importance which has been ascribed to constitutional malnutrition as regards the origin of the disease be borne in mind, and the great value which should consequently be attached to the general condition of the patient, it will easily be understood that the question whether the effect is to strengthen or debilitate should hold a large place in the consideration of climatic treatment" The exciting or strengthening effect of a climate and the weakening or sedative effect are often confused "The exciting or sedative effect is dependent upon the condition of the nervous and vascular systems" and the state of the respiratory passages as respects irritation, while the fortifying or debilitating effect is determined by the nutrition and strength of the individual True, the exciting and strengthening or the sedative and debilitating effect may be united in the same climate, but this combination is rare Egypt, whose climate is most exciting, is, at the same time, weakening On the contrary, Madeira has a sedative and fortifying climate Algiers and the Riviera are, like Egypt, exciting but not tonic Such are Jaccoud's conclusions concerning these popular health resorts, while, on the other hand, he considers Meran and Montreux invigorating as well as exciting If the climatic effect be too exciting, it is seen "in physical and moral agitation, in susceptibility which is so pronounced as to be painful, in continuous insomnia, often in headache, acceleration or irregularity of the respiratory and circulatory rhythm, and lastly, and undoubtedly, in irritability of the larynx and bronchial tubes" The conditions necessary, then, to a desirable result are "meteorological uniformity in every sense, with absence of dust as respects the local, and fortifying action, with little or no exciting influence, as regards the general effect"

In conclusion of this subject we give a summary of the various health resorts which Jaccoud classifies under his several groups Falkenstein, in the Taunus, at a height of 1,640 feet, Gurbersdorf, in Silesia, 1,830 feet, Aussee, in Styria, 2,300 feet, Gaudal, in Norway, 2,640 feet, Davos Platz, in Switzerland, 5,100 feet, Samaden and St Moritz, in Switzerland, in the upper Engadine, 5,720 and 6,090 feet, are comprised in the first group Though the first four do not have an altitude sufficient to confer immunity from phthisis, they have other characteristics that render them beneficial when the higher resorts are not advisable Méran and Montreaux are invigorating and slightly exciting Madeira is strengthening but sedative Egypt, Algiers, Sicily and the Riviera are exciting and but slightly tonic, while Pau and Pisa possess negative qualities

In endeavoring to summarize so important and discursively considered a subject as is this portion of Jaccoud's work, we have necessarily omitted much of great interest, and we would recommend such of our readers who are specially concerned in this question to peruse the author's own words It would be well if someone would carefully investigate the climatic possibilities of our own health resorts, and give the profession the benefit of his conclusions

SOME POINTS IN THE TREATMENT OF UTERINE FIBROMYOMATA

At the meeting of the British Gynæcological Society, on April 22, 1885, Dr Thomas More Madden, of Dublin, read an interesting paper, entitled "Some Points in the Treatment of Uterine Fibromyomata" After making the general assertion that "every growth of this kind is primarily an interstitial myoma, which in the course of time becomes more or less fibrous in structure by the development of its connective tissue, and which may eventually be either subperitoneal or submucous," Dr Madden considers the advisability of abdominal operations, the less heroic measures, such as enucleation and "removal by traction," and concludes with a discussion of the medical treatment of these cases

In a gynecological experience of upwards of fifteen years, in the Mater Misericordiæ Hospital and the Dublin Provident Infirmary, Dr Madden has seen few cases of fibromata which indicated either hysterectomy or oophorectomy He is inclined to think that "the enormous proportion of such cases met with in the practice of other surgeons must, in some degree at least, be the self created result of the preconceived views of those who now find these operations so generally necessary, and may be traceable to the analogy instituted between uterine and ovarian tumours," and characterizes the frequency of such operations as "evidence of the spreading *cacoethes operandi* prevalent among abdominal sectionists" Dr Keith's recently recorded 38 cases of hysterectomy, with only three deaths, yield a mortality of eight per cent, while the mortality of an ordinary uterine fibroid, if left alone, does not approximate this figure The ghastly lists of hysterectomy, with a mortality of one death in every two, three or even five, are not justifiable

Schroder's operation of myotomy yields an appalling mortality In his first series of cases, Schroder lost 30 per cent of his patients, in his second series, 22 per cent Dr Madden regards oophorectomy, for checking metrorrhagia, as unjustifiable "until other and safer methods of controlling uterine hæmorrhage have been fully and unsuccessfully employed" The removal of the uterine appendages in cases "of quiescent fibroids, largely occupying the abdominal cavity, in older patients is difficult, hazardous and frequently impossible The scope of the operation, with which the names of Battey, Goodell, and Knowsley Thornton are so prominently identified, is comparatively limited For the operative procedures, thus briefly discussed, Dr Madden proposes to substitute enucleation *per vaginam*, removal by traction — Emmet's operation — and *ecrasement*

In cases of non-encapsuled myomatous growths, medical treatment may be instituted with some hope of utility The first indication is to arrest the hyperæmic condition, which accompanies the development of the neoplasm, and which causes the metrorrhagia Rest during the menstrual period, sulphuric acid with liquor ergotæ, Dover's powder and gallic acid, or hazeline may be tried Dr Madden states that during the past eight years, he has employed ergotine, or liquor ergotæ, hypodermatically to fulfil this indication, and has no hesitation in saying that we may thus control any hæmorrhage, however extensive, caused by uterine fibro myoma The persistent and judicious use of hot water, uterine irrigations constitute an invaluable adjuvant The second indication is "to stimulate the activity of the local absorbents so as, if possible, to induce diminution of the tumour" Iodide of potassium, the bromides of ammonium and potassium, small doses of tincture of iodine, chloride of calcium in the form of the old solution of the hydrochlorate of lime of the Dublin Pharmacopœia, and the use of iodated and bromated mineral waters are the more important therapeutic resources Of all drugs, iodide of potassium, given in as large doses, and for as long a period of time as can be tolerated, is the most useful Kreuznach, Wildegg or Schinznach are suitable spas

Dr Madden's views, as thus briefly detailed, represent fairly well the doctrines of the more conservative class of gynæcologists, and are in sharp opposition to the practice of Schroder, Martin, Carl Braun, Lawson Tait, Dr Bantock, Mr Keith and Knowsley Thornton The lively discussion, elicited by the paper at the regular meeting of the Society on Wednesday, May 27, 1885, will be productive of much good Mr Lawson Tait opened the adjourned debate with a characteristic incisive criticism of Dr Madden's paper He claimed that the actual mortality of uterine myoma was not known, but that it was very much greater than Dr Madden's paper would lead one to suppose "The medical treatment of uterine myomata is a myth" "It is very much like the chapter in the History of Ireland about snakes—there are no snakes in Ireland" The operation of enucleation, as portrayed by Dr Madden, deserves the application of the word "butchery" As to "oophorectomy," Mr Tait says "My mortality in removing the appendages for myoma in the early stage is, in my recent experience, absolutely *nil* If a woman under forty has myoma, the removal of her appendages before she is profoundly anæmic will cure her in ninety cases out of a hundred, and there is not one per cent of risk in the operation"

Dr Bantock entirely concurred with the views of Mr Lawson Tait Dr Madden's account of the pathology of uterine myoma was as peculiar as erroneous "Every fibroid tumor is not primarily interstitial" In support of his views of the value of operative procedure, he exhibited specimens of uterine tumors, six being cases of supra-vaginal hysterectomy, and two removal by abdominal section and enucleation

The Society adjourned without finishing the debate The subsequent developments will be awaited with interest Apart from the valuable character of the discussion as bearing upon a subject of great practical importance, the tone of the criticism, while incisive and severe, is eminently impersonal and fair

CHEMICAL TESTS FOR CANCER AND SARCOMA

In another department of the JOURNAL of this week we give an account of the chemical examination of the blood of two patients affected with malignant tumors, which were operated upon by PROF. EDMUND ANDREWS. The examination was made in order to test the assertions of Ernst Freund, of Vienna, who has been led, by investigation into the chemical nature of malignant tumors, to believe that they can be diagnosticated by the presence of certain substances in the blood. He found that in patients affected with carcinoma the blood contained a considerable quantity of sugar, and that in sarcomatous patients the blood contained no sugar, but peptone, which, on the other hand, is not present in the carcinomatous. The great clinical importance of any such test, if it can be shown to be trustworthy, is evident at a glance. In many cases one of the most puzzling problems that the clinician has to meet is the diagnosis of tumors in internal organs. But by the aid of Freund's test, if it be reliable, a diagnosis would be comparatively easy.

The cases reported by Dr. Andrews are confirmatory so far as they go. Similar tests should be made not only of the blood taken from tumor patients, but of that from others. Freund's researches were extensive, but require corroboration by most careful investigation. Peptone has been found in the urine of patients with carcinoma of the stomach by Maixner. In order to find its way into the urine, it must have existed in the blood. This does not agree with the observations of Freund, who declares that it is absent in cases of carcinoma.

It is commonly asserted that peptone is present in the urine (and therefore in the blood) in those in whom pus is forming and being absorbed. May not at times the breaking down and suppuration of a carcinoma thus cause the presence of peptone in the blood? The matter is certainly worthy of careful experimentation. Of course, in making these tests in cases affected with tumors, the coincident occurrence of diabetes mellitus on the one hand, and of leucæmia and of collections of pus on the other, must be eliminated.

In making the tests for peptone, Freund used those commonly employed in urinalysis. The method he employed in order to detect sugar in the blood was as follows: He took about four cubic centimetres (one drachm), which he diluted with water, and after some time decanted, then added, in order to precipitate the albuminates, a few drops of a solution of chloride of iron and acetate of soda. The liquid was warmed, exactly neutralized by a solution of caustic potash, and finally filtered. With Fehling's solution it then gave the characteristic reaction of sugar. In some cases it was found that glycerine was present in the blood, but not sugar. This fact is shown when no sugar is found in a suspected specimen, by adding dilute hydrochloric acid, warming the mixture for a little while, again neutralizing it, and using Fehling's test, the glycerine, by this process, having been converted into sugar.

Perhaps a simpler method is that which Pavy has recommended for the detection of sugar in the blood of diabetics. It has proved convenient and trustworthy in the hands of Professor Long, of the Chicago Medical College, who made the tests for Dr. Andrews. Pavy's method consists in the precipitation of albuminates by the addition of sodic sulphates in crystals and concentrated solution to the blood. The mixture is boiled and filtered. The liquid is again boiled with excess of Fehling's solution, when the characteristic reaction will occur if sugar is present.

PROGRESS OF PUBLIC SENTIMENT.

Evidences are not wanting that the principal performers in the grand comic play of "Much Ado about Nothing," which was commenced so brilliantly on the 29th of June by 28 prominent members of the profession in Philadelphia, are becoming weary of their work. Some who were induced to join in the play from the first impulse have already withdrawn, and others are evidently preparing to follow.

Dr. John H. Packard, of Philadelphia, who was appointed Secretary-General of the Congress by the Committee of Arrangements at the meeting in Chicago, and whose name was published as one of the 28 who declined to accept any place in the revised organization, has recently withdrawn his declination and accepted the position. As an offset to the other 27 who started the scheme of obstruction and factious opposition in that city, we have the names of 70 prominent members of the profession in the same city who have freely endorsed the action of the American Medical Association, and pledged their support to the organization of the International Medical Congress of 1887. Among them are the names of teachers and authors as eminent and as well known both in this country and in Europe, as any of those who so hastily declined. To the same endorsement and pledge are appended the names of several hundred prominent and well known members of the profession in other parts of the State of Pennsylvania.

For further evidence of public sentiment in the same direction, the reader is referred to the resolutions in the present number of the JOURNAL passed by a joint meeting of the North-Eastern and North

Western Ohio Medical Societies, which embrace the profession in about forty counties of that State

The idea that the Committee of Arrangements will not be able to complete the work of preliminary organization at its coming meeting on September 3d, or that the vacancies in the several Sections cannot be filled with men of the highest standing and ability, is simply absurd And if the changes are made in the rules that were indicated in the JOURNAL of August 8, there will not be left the vestige of a foundation on which opposition can rest, except that afforded by personal prejudice alone

DR W K BOWLING, one of the ex-Presidents of the American Medical Association, and one of the most eminent members of the profession in the Mississippi Valley, died quite suddenly at his residence, on Cumberland Mountain, near Nashville, Tenn , on the morning of the 6th of August, 1885 Dr Bowling was one of the pioneers and a leader in all that pertains to the educational, social and practical interests of the medical profession in this great interior valley He has taken his departure at the ripe age of 77 years A suitable biographical sketch will appear in our columns at an early day

SOCIETY PROCEEDINGS

AMERICAN OTOLOGICAL SOCIETY

The Eighteenth Annual Session of the Society was held at the Pequot House, New London, Conn , July 14, 1885, the PRESIDENT, DR C H BURNETT, of Philadelphia, in the Chair

DR SAMUEL SEXTON, of New York, read a paper on

INFLAMMATION OF THE ATTIC OF THE TYMPANUM

The subject was discussed under two headings, acute and chronic inflammation of the attic The latter presents itself in the form of deep sinuses containing polypoid tissue, crusts, pultaceous matter, etc , leading from the inner end of the canal up into the attic into the antrim, and sometimes through the membrane flaccida This is often the result of acute inflammation in early life The atticus tympanicus is that portion of the tympanum lying above a plane extending transversely from the prominence on the inner wall, formed by the external semi circular and facial canals to the auditory plate on the outside Beneath this plane lies the atrium tympanicum Over the attic arches the tecmin, which also covers the antrum, the petro mastoid canal, a varying number of cellules, and the Eustachian tube The attic communicates freely with the antrum by means of the petro mastoid canal of Sappey The mastoid antrum lies behind and to the outer side of the attic in the spongey substance of the mastoid *It* is usually larger than the attic, and, as a rule, extending downward among the cellules of the mastoid process, giving *off frequently* a small passage, communicating with the cellules overlying the external auditory meatus The attic is divided below into two compartments by the incus and malleus, the cord, ligaments, etc These compartments communicate freely with each other, with the atrium, the Eustachian tube, and with the antrum These cavities are lined throughout with mucous membrane

Acute inflammation of the attic may follow catarrh of the head, the exanthemata, and the entrance of fluids propelled along the Eustachian tube The very frequent occurrence of inflammation of the attic from this cause is readily accounted for when we remember that the Eustachian tube at its tympanic orifice opens by a free sweep into the attic as well as into the atrium Inflammation of the attic may be simultaneous with, consecutive to, or independent of, inflammation of the atrium It is the more serious from the fact that swelling of the mucous membrane clogs the outlets and prevents drainage In such cases, the membrana flaccida is red, the vascular turgescence extending above into the external auditory canal and sometimes downward about the short process of the mallet Should the disease progress further, the inflammation may extend beneath the marco tympanicus of the auditory plate, followed by effusion of serum and blood which presses away the membrana flaccida and integument of the canal, producing a bulging sac so great sometimes as to entirely conceal from view the membrana tympani, and may entirely fill the canal and present at the lumer as a purplish tumor

Periostitis of surrounding parts may occur and extend along the surfaces of the canal, mastoid or squamous portions of the temporal bone Inflammation may extend downward to the atrium, but as long as this does not happen and the membrana tympana is unaffected, there may be little deafness, though autophonia may be present Inflammation, as a rule, extends into the antrum and mastoid cellules If the escape of secretions into the antrum or Eustachian tube is prevented, the case is more severe and the extension to the cranial cavity more to be feared Inflammation of the antrum often persists after the tympanum has healed, drainage taking place through the Eustachian tube or by a sinus through the cortex of the mastoid

The subject of treatment resolves itself into a question of drainage, and the employment of such constitutional remedies as aconite and calx sulphurata, which tend to check the inflammation and prevent the formation of pus

Owing to the impossibility of making an accurate differential diagnosis between the pains of pachymeningitis and neuralgic pains of otitis media, we should be cautious about trephining the mastoid where pain is our only indication It is useless to perform this operation after pachy-meningitis has developed Moreover, this question is one which, in any given case, must be left to the judgment of the attending surgeon

DR D B ST JOHN ROOSA, of New York, said that the remedies mentioned, mercury and calcium sulphide, are not in common use in the way recommended by the speaker I have used mercury in dose of one-tenth to one fifth grain, and also sulphide calcium, without any good effect' I should like Dr Sexton to describe a case, indicating the manner in which he would use these remedies

DR SEXTON said that the remedies are given in small doses, but these are frequently repeated In this way the effect is quickly obtained The moment there are symptoms of purulency I use the calcium sulphide, and I think it controls the process I have seen congestion and swelling over the mastoid disappear under the use of the calcium

DR J A ANDREWS, of New York, had had a case in which the inflammation was most intense in upper part of the tympanic cavity, and a perforation was established between mastoid antrum and external auditory canal When I saw the case there was great deal of swelling of the external auditory canal A fluctuating swelling in the superior posterior part of the canal was incised and considerable blood and pus escaped The patient made a good recovery

DR O D POMEROY wished to know if Dr Sexton believed that the administration of mercury in acute inflammation relieves this pain, and if he does what is his theory of its action?

DR SEXTON said that he had never recommended it to relieve pain For the relief of pain he would recommend the use of aconite and pulsatilla, especially as there is no danger of a cumulative action with it Four or five drops of the latter may be added to a wine glassful of water and a sip taken every fifteen or twenty minutes The sulphide of calcium given alone will relieve pain

DR C R AGNEW said that when there is acute otitis media it is desirable to cut it short as soon as possible I would ask Dr Sexton what he would do in a case of otitis media catarrhalis in an infant six months old

DR SEXTON In such a case I should examine the history, ascertain the general condition, ascertain whether it was subject to catarrhal trouble, ascertain the condition of dentition, ascertain whether there had been a previous attack of inflammation of the middle ear If there were accumulation, I should let it out, but in the majority of cases at this age, the membrane has already ruptured when the case is seen If there were suppuration I should give calcium sulphide If there was simply catarrh, I should give mercury

DR CHAS J KIPP, of Newark, was surprised to hear nothing said of inflation of the middle ear, this relieves the pain Where there is protrusion in front of the membrane, incision gives relief to the suffering

DR SAMUEL THEOBALD, of Baltimore, has found the instillation of a warm solution of atropia of great service, a solution of the strength of four grains to the ounce With this cathartics may be combined with great benefit Pyro phosphate of sodium in fifteen grain doses every two hours, keeping it up for four or five days, is also beneficial After perforation of the drum membrane I would recommend the use of boracic acid

DR CLARENCE J BLAKE, of Boston, said that there was one anatomical point which had not been referred to by Dr Sexton, and that was the reduplication of the mucous membrane in the upper portion of the tympanic cavity These serve to separate the upper portion of the tympanic cavity from the lower, and they become an important element in inflammation of this part, and may tend to retain secretions

DR SEXTON said, in conclusion, that he had used mercury and the sulphide of calcium for the last ten years, and he was convinced that they are beneficial in a certain number of cases

DR W W SEELY, of Cincinnati, read a paper on

THE TREATMENT OF CHRONIC OTITIS MEDIA

Of late years more attention has been concentrated on naso-pharyngeal affections as the starting point and continuing cause of this trouble At this point attention was called to the possibility of treatment of ordinary pharyngeal troubles giving rise to ear complications Every one knows the disastrous results following the treatment of nasal catarrh The great difficulty in these cases is to so treat the nose and throat as to benefit the tube and middle ear He alluded to the abandonment of the nasal douche and the posterior nares syringe, and held that all applications to the naso pharynx should be made with care, as all were liable to do harm All of the points thus far were to justify the author's condemnation of the slurring of these cases by specialists in various ways, such as putting the catheter or balloon into the hands of the patient or parents, throwing over the treatment of the throat also to the patients He claimed that this class of cases were almost all amenable to treatment, and only time and patience were necessary to manage them

The speaker thought that the attention of the general profession was becoming too much centred on the Eustachian catheter as the only means of treatment, and especially as the only means of opening the tubes Often catheterization does harm rather than good, and some application of boric acid and vaseline, or what is still better, of the yellow oxide of mercury and vaseline, through the nostrils, will open the tubes when the catheter has little or no effect He said that salves had almost, if not quite, supplanted all other applications for nasal and naso pharyngeal troubles

Dr Seely concluded his remarks with the following

1 That only experience of sufficient length of time (often lasting over months) in each case, can determine whether treatment shall be continuous (daily) or interrupted, *i e*, perhaps daily for a week, followed by an interruption of some weeks or months

2 Only experience in each case can inform us whether treatment is to entirely directed to the middle ear, or entirely to the naso pharynx, or combined against both

3 Only experience in each case can inform us whether injections into the cavitas tympani are called

for Under this head it was stated that direct medication either of the middle ear or naso-pharynx, as routine treatment, was unwise, till simple inflation had failed

4 Mechanical dilatation of the tubes is rarely necessary or advisable Only in extremely dry states of the tube is dilatation followed by much success

5 Hearing tests are not reliable, and hence patients with great deafness, great loss of bone conduction, etc , should not be sent away till the test by trial has been gone through with

6 Simple inflation failing, the greatest attention should be given to the naso-pharynx, even though it is in an apparently fair condition

7 Syringing, douching and swabbing the naso pharynx should be abandoned

Dr Charles H Burnett, of Philadelphia, read a paper on

THE RELATIONS BETWEEN CHRONIC CATARRHAL OTITIS MEDIA AND CHRONIC RHINITIS

Dr Burnett had found a constant causal relation between chronic catarrh of the middle ear and chronic rhinitis and rhino pharyngitis The latter is chiefly of the hypertrophic form The atrophic form, which is made to include the fibrous degenerations and the sclerotic forms, as well as the truly atrophic, with shedding of epithelium and exposure of basement membrane, constitutes about 14½ per cent In the first class the appearances of the membrana tympani are very diversified, so much so as to preclude a predication of the state of the middle ear and hearing from them alone In the atrophic class the symptoms presented by the membrana tympani are more uniform, and the surgeon is able to predicate from them more precisely concerning the aural disease Yet, on the whole, the appearances of the drum taken by themselves, can not aid greatly in the diagnosis of chronic aural catarrh The faucial symptoms play a very subordinate part in diagnosis in chronic catarrh of the middle ear, because faucial and throat disease have little or no causal relationship to aural disease

Tinnitus aurium is more marked in the atrophic class than in the hypertrophic, as a rule There is also a greater patency of the Eustachian tube in the atrophic forms of aural disease than in the hypertrophic, though it is found in both forms of naso-aural disease It is most relieved by treatment of the nares and naso-pharynx

The treatment in the first class should be by cleansing and astringent sprays, with applications of preparations of iodine, never stronger than half and half Nitrate of silver is not to be used in hypertrophic rhinitis In the atrophic form, cleansing, the removal of inspissations if they occur, and then the application of stimulant sprays, preferably nitrate of silver, not stronger than four grains to the ounce of water, is the proper treatment

In regard to the use of the galvano cautery in the nares, caution should be exercised, since it may lead to inflammation in the naso pharynx and middle ear

Dr Agnew said that it is impossible to apply salves to the whole of the diseased surface by means of Bowman's probe He has used the nasal syringe for twenty years, and is not prepared to accept the law that it should be abandoned He is more willing to agree with the views of Dr Burnett, but thinks more stress should have been laid on the importance of hygiene, which is the most important element in the treatment

Dr Roosa thought that the only benefit to be obtained in the majority of these cases is from proper hygiene He thinks that we do not need to continue our examinations very long to determine whether or not we may expect to give the patient any relief If he find diminished tone conduction, he thinks it unnecessary to go on and treat that patient

Dr E Williams, of Cincinnati, said that he used the Eustachian catheter in every case where he thought it indicated Often introduce a flexible bougie through the catheter sometimes into the middle ear In some cases of stricture of the tube this is quite useful

Dr Knapp said that he had lately suffered with a catarrhal affection which at times caused him considerable annoyance He had employed a salve of iodoform with vaseline with considerable advantage

Dr Seely said that salves remain longer in contact with the affected part than do solutions, thus giving a more decided effect

AFTERNOON SESSION

Dr Sexton presented

A CONVERSATION TUBE FOR THE AURAL INSTRUCTION OF DEAF MUTES

By means of a thin mouthpiece the patient was able to hear his own voice and compare it with the voice of his teacher

Prof Graham Bell called the attention of the Society to the great number of children who were classed in institutions as deaf mutes, but who, under proper treatment and education, could be made simply hard hearing members of society

Dr Charles J Kipp then reported

A CASE OF FATAL EAR DISEASE, BEGINNING AS A CIRCUMSCRIBED INFLAMMATION OF THE EXTERNAL AUDITORY CANAL

The patient, a married woman, aged 28 years, was first seen nine months before her death Since the previous confinement, which occurred four months before coming under observation, she had suffered occasionally with severe pain in and about the left ear There was swelling and redness of the posterior upper wall of the external canal There was no perforation and no otorrhœa Under the use of leeches, instillations of morphia and inflation of the middle ear, there was decided improvement in the course of a month, when she passed from under observation Eight or nine months later, the pain again appeared, shortly after a confinement This was due to furuncles and rapidly disappeared There was no affection of the middle ear Paracentesis was performed, but no escape of fluid took place The patient recovered from the ear trouble, but subsequently died

The autopsy was made by a physician in Maine.

At the autopsy there was found evidence of intense inflammation over the entire extent of the arachnoid and pia-mater There was a collection of pus immediately over the posterior surface of the petrous portion of the temporal bone Pus was also found on the pons varolii A small abscess was found in the anterior part of the left lobe of the cerebellum near its junction with the pons The mastoid cells were filled with pus There was only a thin exudation in the middle ear

DR C H BURNETT read a paper on

THE LOCAL USE OF COCAINE AND BRUCINE IN DISEASES OF THE EAR

Had used both the sulphate and hydrochlorate of cocaine to produce anæsthesia in painful affections of the ear Neither were efficient when the pain was due to inflammation in the dense tissues of the external auditory canal, as in furuncule of this part, nor when acute inflammation occurred in chronically thickened periosteal and mucous tissues in the tympanic cavity A four per cent solution of the hydrochlorate of cocaine, however, is efficient to induce local anæsthesia in cases of not excessive congestion of the skin of the fundus of the auditory canal and in the membrana flaccida of the drum membrane, as is observed in acute coryza, and attended with pain of a not continuous or intense variety But solutions of cocaine are not competent to produce local anæsthesia in the external auditory canal, profound enough to permit painless incision into it Local anæsthesia in the membrana tympani preparatory to paracentesis is not required, as the operation is not painful enough to demand local anæsthesia A solution of brucine, the alkaloid or the nitrate, is successful in relieving pain of ear disease A 5 per cent solution may be employed

DR E E HOLT, of PORTLAND, Maine, read a paper entitled

DOES COCAINE HYDROCHLORATE, WHILE RELIEVING THE PAIN IN ACUTE OTITIS MEDIA, PROLONG THE CONGESTION?

This question had occurred to him several times where he had used the remedy for the relief of pain in the middle ear He was satisfied that while cocaine relieves the pain and for the time holds the inflammation in check, yet after the effect of the remedy passes off, the inflammation goes on unaffected

DR THEOBALD had found that in the nasal passages the drug exerted a similar effect, that although it at first relieved congestion, yet the congestion returned and was even greater

DR J O GREEN had come to the conclusion expressed by Dr Holt

DR POMEROY recommended that in using the cocaine, the solution should be applied by means of a dossil of cotton, which is to be allowed to remain in position for ten or fifteen minutes

DR D B ST JOHN ROOSA read a paper on

PRESBYKOUSIS

The reader applied this term to the failure of hearing which is incident to old age, and which is not dependent upon inflammatory affections It comes on after the age of forty or fifty years Such persons hear badly in a noisy room They hear the watch badly, but in a quiet room they can hear quite well This is characteristic of this affection In inflammatory troubles with the ear, the person often can hear pretty well in a noise, while in a quiet room he hears badly These three symptoms go together diminished tone conduction, hearing worse in a noise, and the disproportion between the ability to hear the voice and the watch The conditions on which this presbykousis is dependent have not yet been determined, for as yet there have been no opportunities for post mortem examinations

DR E E HOLT had examined a large number of persons with ear disease who claimed that they could hear better in a noise than in quiet, but was unable to find that this was a correct observation In noisy places, the voice is raised, and this might account for it

DR ROOSA, in conclusion, said that in regard to the hearing better in a noise, he was convinced that patients with tympanic disease could hear better under such circumstances, and cited the example of a lady who heard with difficulty under ordinary circumstances, but who in a boiler shop, heard the ordinary voice distinctly, while her husband, with normal hearing, heard only when words were shouted

DR SEXTON exhibited a *Glass Ear Syringe and an Ear Forceps with Several Attachments*

DR E DYER, of Newport, R I, reported a case of *Fistula of the Helix in a Girl of Fourteen* which he *greatly benefited by the application of the galvano-cautery*

The following were elected

OFFICERS FOR THE ENSUING YEAR

President, Dr J S Prout

Vice-President, Dr S S Sexton

Secretary and Treasurer, J J B Vermyne, New Bedford, Mass

Publication Committee, Drs Vermyne, Blake and J O Green

Committee on Membership, Drs Carmalt, Kipp, and Theobald

Dr F L Capron, of Providence, R I, was elected to membership

The meeting then adjourned

CHICAGO GYNECOLOGICAL SOCIETY

Meeting, Friday Evening, June 19th, 1885

THE PRESIDENT, H P MERRIMAN, M D, IN THE CHAIR

PROFESSOR J H ETHERIDGE read a

REPORT OF A CASE OF A FŒTUS ENCLOSED IN ITS SISTER'S PLACENTA—(FŒTUS COMPRESSUS, FŒTUS PAPYRACEUS,)

with exhibition of the specimen

On 26th September, 1882, Mrs F J B, 22 years old, of a nervous sanguine temperament, healthy, was delivered of a mature female child, after a normal labor of four hours duration During the delivery of the placenta, some abnormity was detectable, which proved to be a *fœtus papyraceus*.

The outer surface of the placenta at once arrests attention. A deep furrow separates the two placentæ, which are united, on their amniotic surface, by a series of compact white bands, discoverable only by pressing through the furrow. The large placenta constitutes about two thirds of the entire mass. The smaller placenta is thin, flat and compact, being about one third as thick as the larger one. The placenta of the living child is normal throughout its extent. Cotyledons are well marked, the tufts and villi presenting normal microscopical characters. The placenta of the *fœtus compressus*, in about nine-tenths of its extent, is whitish yellow, and very firm. The whole thickness of this portion of the placenta, excepting its amniotic surface, presents one unbroken mass of fatty degeneration. The remaining one tenth of the placenta presents a carneous appearance, evidently a transition stage between normal placenta and complete fatty destruction. Its cotyledons are enmassed and its tufts and villi solidified and the whole is interspersed with initial fatty depositions.

As regards the fœtal surface of placenta, the two segments were wholly different at time of birth. The placenta of the living child presented a normal appearance. The placenta of the *fœtus papyraceus* presented the appearance of a closed bladder, which, upon examination, was found to be an unruptured amnion, containing amniotic fluid and a fœtus. The development of the *fœtus compressus* corresponded to the third month. The cord of the *fœtus papyraceus* was ten cm. longer than that of its fellow, and much thinner. The cord was inserted into the margin of the placenta, near the fully developed organ.

Among the causes, producing the death of the fœtus, the following may be mentioned:

1. Faulty insertion of the cord, at the margin of the placenta, adjoining its fellow. (Kieselhaused.)
2. Faulty structure of the cord, thin, twisted, or deficient in the jelly of Wharton. (C. Braun.)
3. Disease of the placenta.
4. Traumatism.
5. The implanting of the umbilical vessels too closely together, and arterial anastomosis.

Fœtus papyraceus is of seldom occurrence. A search through the library of the Surgeon General's office at Washington resulted in finding only five references to reports of similar cases.

DR. PHILIP ADOLPHUS thought that such cases were of more frequent occurrence than the remarks of the author of the paper would lead one to believe. In twin pregnancy, the death of one fœtus before parturition was not infrequent.

PROFESSOR W. W. JAGGARD agreed with Dr. Adolphus that while such cases were rare, a more extended research into the literature of the subject would have revealed a much larger number of cases. While it was true that American and English text-books usually merely mentioned the fact of occurrence, German, French and Italian treatises devote a chapter to the subject. The last edition of Schroder, contained an excellent *resume* of the literature. The case, reported and exhibited by Professor Etheridge, resembled in many points the case in the Pathological Museum of the Jena Lying-in Hospital, fully described by B. S. Schultze. This specimen showed the placenta of a mature fœtus, and adjoining it a second egg, corresponding to the sixth week of pregnancy, with its own decidua and unruptured amnion.

Professor Etheridge's case was chiefly interesting, as bearing upon a subject of theoretical importance, *i. e.*, superfecundation, and superfœtation. On *á priori* grounds, it was possible that superfœtation could occur as late as the twelfth week of pregnancy,—when *decidua vera* and *reflexa* became united. Up to this time, it was possible that egg and spermatozoid might come in contact. Superfœtation was also possible in cases of double uteri. Up to the present time, however, no case has been recorded which does not admit of a simpler explanation. There exists a great weight of evidence in favor of superfecundation. Mares give birth simultaneously to horse and mule foals; bitches, running the period of rut with different breeds of dogs, throw young of different, so called bastard forms, corresponding to the breeds of the male progenitors; the same is true of cats. A woman may give birth to twins, one of which is white, one black. The latter fact, however, does not necessarily demand for its explanation intercourse at or near the same time with a white and a black man, since in crossing races, the offspring may resemble either father or mother, or one child may resemble the male, the other the female progenitor. There could be no reasonable doubt as to the accuracy of Professor Etheridge's diagnosis.

DR. JOHN BARTLETT had seen one case of *fœtus compressus*, in the Chicago Woman's Hospital, about four years ago. One fœtus was mature,, the other corresponded in development to the fifth month of pregnancy. Professor Bartlett referred to the contribution of Smellie and Mauriceau upon the subject.

DR. EDWARD WARREN SAWYER referred to the fact that in ectopic pregnancy no compression of the fœtus was observed. He alluded to a case in which he performed laparotomy three and one-half years ago. The fœtus weighed eight pounds. There could be no question about superfœtation in Professor Etheridge's case. Fœtation by inclusion might be considered as explanatory of many of the monstrosities which are so commonly seen.

PROFESSOR DANIEL T. NELSON though it would be interesting to know how much force was necessary to compress the fœtus as in Professor Etheridge's specimen. He referred to the experiments of Professor Park, of the Massachusetts Agricultural College, in the determination of the expansile force of growing squashes and pumpkins.

THE PRESIDENT wished to know whether the death of the fœtus occurred before compression, or whether it resulted from that factor. The marginal insertion of the cord doubtless was an important etiological agent. When the uterus was in the pelvic cavity, compression was greater. He referred to the fact that in twin pregnancies it was unusual to find both children equally developed, and frequently the birth of one preceded that of the other by minutes, hours, and even days

DR HENRY T BYFORD read a report of a

CASE OF LEIO-MYOMA OF THE VAGINA AND UTERUS

The patient was a widow, about thirty-five years old Was married ten years without becoming pregnant She had no decided symptom of disease except an occasional backache, some leucorrhœa She was treated for uterine inflammation three years before, and no tumor was discovered Since that time she has menstruated every two weeks Catamenia usually lasted five days, and were normal as to quantity Twelve years ago she noticed a tumor about the size of a hickory nut, just within the vagina This swelling had since that time grown steadily, until its protrusion from the vagina, about 12th of Jan , 1885, caused great inconvenience Even at that time the pain was promptly relieved by an opiate administered by Dr Doering Two or three days subsequently the tumor became black, swollen, and emitted a gangrenous odor Slight septicæmia followed cauterization with nitric and carbolic acids The tumor was attached to the anterior walls of the vagina

The tumor was subsequently crushed off, and the patient recovered Examination revealed a protuberance, about the size of a goose egg, upon the right anterior surface of the uterus, which was apparently a leio myom

The following points of interest are to be noted in connection with the case 1 The occurrence of both tumors in the same person, 2 The slow growth of the vaginal as compared with the uterine tumor, 3 Sloughing of the capsule immediately after protrusion from the vagina, without impairment of the vitality of the tumor proper, 4 Entire absence of sensitiveness to strong acids, 5 The production of a pedicle by ligaturing the proximal end with a fine wire , 6 Sterility antedating the discovery of the uterine tumor, 7 The influence of ergot upon the uterine tumor

DR EDWARD WARREN SAWYER thought that the locality of the vaginal tumor was interesting but not unusual

PROFESSOR DANIEL T NELSON inquired whether or not fibroid tumors occurred by preference in the anterior vaginal wall He thought, as regards the operation, an elliptical incision around the base, and enucleation of the tumor, would have fulfilled the indications equally well

FOREIGN CORRESPONDENCE

LETTER FROM BERLIN

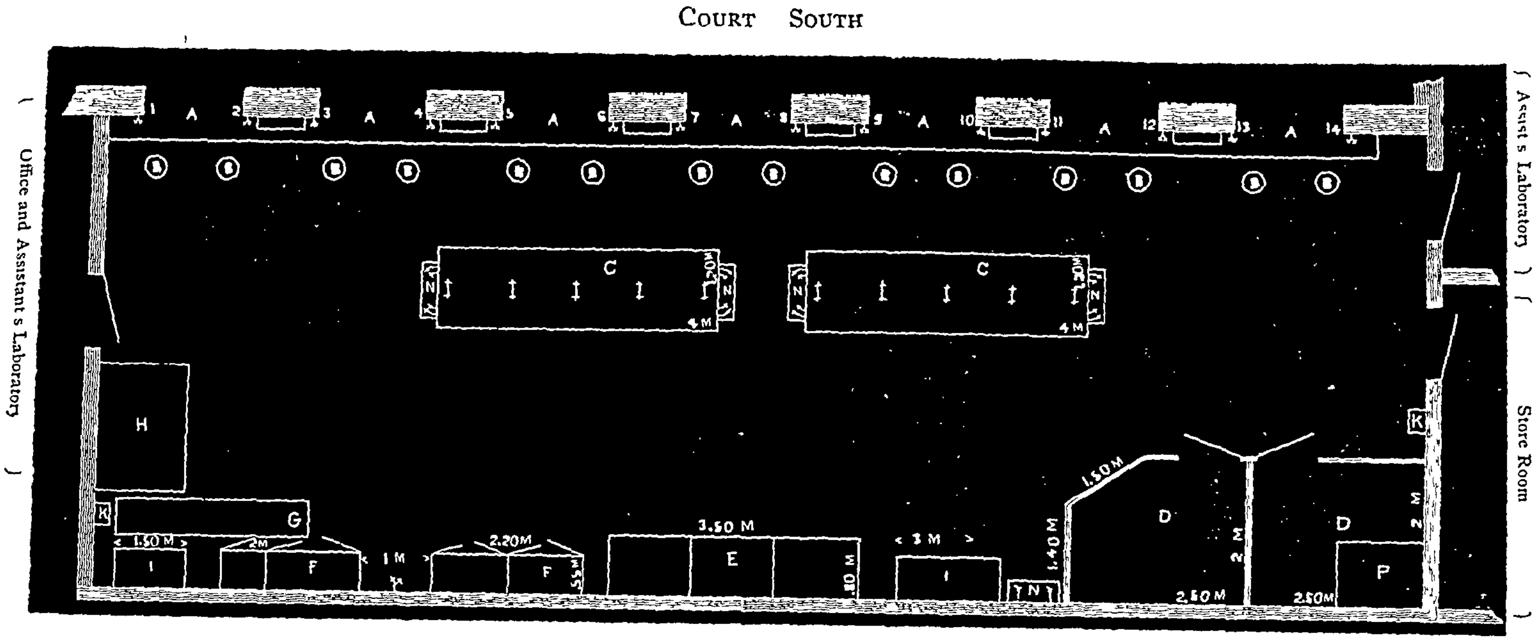
(FROM OUR SPECIAL CORRESPONDENT)

KOCH S BACTERIA LABORATORY

Perhaps some of the readers of the JOURNAL may be interested in a brief description of the new laboratory that has been provided for the great master of bacteria to give instruction in his peculiar branch Prof Robert Koch has just received his appointment as Professor of Hygiene in the Royal University, and in this connection he has to day opened a course in bacteriology for 10 students

The general laboratory is on the third floor of a large old house which has been remodeled, and this, with its appendages, are, as yet, the only rooms finished The laboratory is a large room 18 75 metres long, 6 75 m wide, and 3 50 m high It has seven large windows facing the south and looking out into a central court, the entire building being in the form of a hollow square The entrance to the room is at its east end and in our description we will go around it from left to right Commencing in the southeast corner and extending the whole length of the south side, are the microscope desks (A A A in the plan) formed by a continuous shelf, the top of which is 0 75 metres above the floor, and beneath it is a single row of small drawers which are very convenient for instruments and small apparatus in common use Each window is arranged to accommodate two persons Between the windows are four rows of narrow shelves for regular bottles, specimens, etc , and above these is a broad shelf, on each end of which is a bottle of distilled water, which is brought within easy reach of the student by means of rubber and glass tubing and a clamp to shut it off In addition to a gas-burner high up between each window, every desk has, an inch or so above the table, connections for the attachment of two Bunsen burners, thus giving an ample supply Piano stools (B B B) are provided for use at the microscope desks, which being adjustable, are particularly convenient for persons of different heights

At the west end of the room are two doors leading to the assistant's laboratory and to the storeroom In the northwest corner there is partitioned off a large closet 5 m long and 2 m wide, which is divided in halves (D D) for culture-rooms, each having several rows of shelves around its sides In the one in the corner is a refrigerator to preserve the culture gelatine when not in use, and also other materials for which a low temperature is desirable On the shelves in this closet are kept the jars and test tubes containing cultures on gelatine, the refrigerator keeping the general temperature of the room about right to favor growth of the bacteria, while the temperature of the laboratory itself, during these summer days, is high enough to melt the gelatine and thus spoil the cultures The second culture closet contains the culture-oven, in which are kept those cultures which require a constant and higher temperature, as that of the body Close to the culture closets is a sink (N) with two faucets and then there is one of the large German stoves (I) built of tiles At a distance of three metres from the culture closet is the "hood" (E), 3 50 metres long and 0 80 metres wide, extending to the top of the room This is provided with sliding glass doors which move up and down It is abundantly supplied with gas and has good ventilation Here is kept the steam sterilizer and also the animals, mice and guinea-pigs, which have been vaccinated, and here also can be performed any operation or experiment which it is desirable to have isolated on account of disagreeable odors Near the hood is a large closet (F) 2 20



BACTERIA LABORATORY Length, 18 75 metres, width, 6 75 metres, height, 3 50 metres

A A A —Microscope Desks at Windows
B B B —Piano Stools
C C —Work Desks with Drawers and Closets beneath
D D —Culture Closets with Shelves
E —*Hood with 3 Apartments* and Sliding Doors
F F —Closets with Shelves

G —Demonstration Tables
H —Platform before Blackboard
I —Stoves
K K —Sterilizing Apparatus
N N N —Sink bowls and Faucets
P —Refrigerator

metres long, and one metre distant from this is another (F) 2 metres long These are used for the general stock of chemicals reagents, etc Between these two closets there is on a table a magnificent and delicate pair of scales, which are used only when the greatest accuracy is required, others being supplied for ordinary work

In the northeast corner of the room is another stove (I), in front of which are the demonstration tables (G) used for exhibiting cultures, etc These are beside the platform (H) which is in front of the blackboard used for illustration Fastened to the wall on each of the east and west ends of the room, are two large double walled sterilizers used for sterilizing test tubes, glass plates, etc In the centre of the room are two large work desks, which have a surface measurement of 4 m x 1 20 m and are 0 90 m high, being arranged for standing work Beneath these are a single row of drawers and cupboards which have locks and keys, and are where the students keep their microscopes and larger apparatus On the top of each desk are five double gas connections, and at each end is a large iron sink bowl into which empty four faucets, which are arranged in pairs 30 or 40 centimetres respectively above the top of the desk The floor and desks are made of hard wood As the supply of gas and of water is ample and convenient, and as everything is so conveniently arranged, it forms a very suitable bacteriological laboratory BACTERIA

Berlin, July 25, 1885

DOMESTIC CORRESPONDENCE

THE INTERNATIONAL CONGRESS

Sir —The following preamble and resolutions were passed at the joint session of the North Eastern and the North-Western Ohio Medical Association, and by a separate resolution directed the same to be sent to the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for publication

"*Whereas*, An unseemingly controversy appears in the medical journals of the country respecting the work of the Committee on Organization of the approaching International Medical Congress, and,

"*Whereas*, There has appeared a remarkable readiness on the part of one or two prominent medical journals to present, if not magnify, the difference of opinion which may exist in the medical profession generally, to the disparagement of the work being done by the Committee, instead of aiding in making the work a success, predicting failure and disgrace, and pronouncing the enterprise 'moribund'" Therefore be it

"*Resolved*, That we, the members of the North Eastern Ohio Medical Association and the North-Western Ohio Medical Association, in joint session assembled, regard with solicitude and disapproval, any word or act on the part of any member of the regular profession of the United States which shall tend to create, perpetuate or encourage discord in the work of completing the organization of the International Medical Congress"

"*Resolved*, That no question of local, State or personal consideration or differences have properly any legitimate right to be brought into the question of organization to increase the labors or embarrass the work of the Committee, but that it is the duty of every honorable member of the regular profession to aid in promoting harmony and efficiency in the work of preparing for the International Medical Congress, in the success of which every member of the medical profession in the United States is interested"

"*Resolved*, That as the interest of the whole is paramount to that of the individual, it becomes every one to yield his personal desires or supposed rights to the advancement of harmony and the ultimate complete success of the approaching International Medical Congress And that the refusal to perform duties regularly assigned by the Committee, presenting no adequate reason for such refusal, betrays a spirit unworthy of so great an occasion"

W C CHAPMAN, of Toledo, O, *President*

R E JONES, of Gomer, O, *Secretary*

THE MEDICAL NEWS' VERSION

THE ALLEGHENY COUNTY MEDICAL SOCIETY AND THE INTERNATIONAL CONGRESS

EDITOR JOURNAL AMERICAN MEDICAL ASSOCIATION

Dear Sir —The enclosed note I send to day to the Philadelphia *Medical News* In simple justice I hope it will be published

Editor of News Dear Sir —I notice in my *News* received to day that you make a point of the recent action of the Allegheny Co Medical Society concerning the proposed International Medical Congress Our Society has over one hundred and ten members At the meeting where the resolutions you published were passed not over twenty members were present Of these but few were familiar with the facts in the case The resolutions were scarcely discussed except by the mover As they were passed *viva voce* no record of the vote was kept, but I am assured that not over twelve, or *one-ninth* of the entire Society voted for them To whatever weight that vote may have you are welcome, but simple justice to the profession in this county requires these facts to be stated, as many of those who were absent from the meeting are not in favor of reinstating a Committee two-thirds of whom appointed themselves to one or more of the most desirable positions in the Congress, and who gave other positions of honor to the bitter enemies of the very Association from which they received their authority

Respectfully yours,

THOS D DAVIS,

Cor Sec'y Allegheny Co, Pa, Med Society

Pittsburgh, Pa, Aug 10, 1885

CONSULTATION WITH HOMŒOPATHS

The following correspondence explains itself —ED

TO THE EDITOR OF THE JOURNAL

Dear Sir —I enclose herewith a letter addressed by me to the editor of the *Record* a few days since

You will see he made a perfectly gratuitous attack upon my professional integrity, and when requested, through a perfectly polite note, to publish my denial of it, he attempts to add insult to injury by declining to do so, and pronouncing my note discourteous I beg that you will do me the favor to give my note to Dr Shrady a place in your JOURNAL, in order that I may be set right before my professional brethren

Very truly and respectfully,
A Y P GARNETT
Washington, D C, Aug 2d, 1885

To the Editor of the Medical Record

Dear Sir —Upon my return to the city to day my attention has been called to the following paragraph, which appears in your issue of the 18th inst

> "CONSULTING WITH HOMŒOPATHS —The wife of Mr Bayard, Secretary of State, has been lying ill at Willmington, Del, under the care of a homœopathic physician, Dr Argendank The daily papers assert that regular physicians, among them Dr Gardner (Garnett?), of Washington, have been in consultation with the physician in attendance"

As you are the zealous and aggressive organ of the New Code sect who advocate and practice such professional association, I am constrained to believe that the introduction of my name in this connection was intended as a high compliment to me It is therefore with feelings of the deepest chagrin and regret that I find myself compelled, by a regard for the truth, to confess to you that I have never either seen or spoken with the lady referred to, and consequently could not have enjoyed the privilege of participating in a consultation so unequivocally commended by you

Very respectfully yours,
A Y P GARNETT, M D
Washington, D C, July 24, 1885

My Dear Sir

As your suggested charge that I had been in consultation with a homœopathic physician has been sent broadcast to the professional world, I trust you will recognize the justice and propriety of giving equal publicity, through the columns of your journal, to the enclosed reply

Very truly and respectfully,
A Y P GARNETT
To DR SHRADY
Washington, D C, July 25th, 1885

HYDATID TUMORS OF THE BRAIN

Dear Sir —Permit me to make a brief explanation regarding the kind criticism offered by Prof Osler, of Philadelphia, in Vol V, No 3, of the JOURNAL

In the broad sense of the term, a hydatid tumor means simply a cyst or bag filled with a watery liquid As we have hydatid tumors resulting both from the echinococcus and cysticercus, I defined in the very beginning of my paper the meaning I attached to the term as used in this paper, which was "the intra-cranial occurrence of either the echinococcus or cysticercus cellulosæ in man" In no way could my paper be construed as confounding these two parasites, for I distinctly described each briefly, under divisions A and B (see page 1, Vol V, No 1, of the JOURNAL), and recognized them as two separate species of the same genus, but producing similar pathological changes when they invade the human economy

It seems to me, from a clinical standpoint, it matters but little which one is producing the invasion when the results to the patient are the same In fact, I can readily imagine it to be a *very* difficult task to diagnosticate between these two parasites, on the living subject, especially when they occur in the brain

As to Dr Osler's second criticism, unfortunately from unavoidable circumstances three of the cases were not examined microscopically, even after sending one to a pathologist in Cleveland, who unfortunately lost it before an examination. The fourth, however, was examined microscopically, and a number of isolated hooklets were found (some of which had partially undergone calcareous degeneration), which enabled me to be positive in this one case, at least, and very confident in all the others I reported

Very truly, R HARVEY REED, M D
Mansfield, O, July 25 1885

NECROLOGY

WM GASTON BULLOCH, M D

This well-known physician died at his residence in Savannah, Ga, on June 23, in the seventy-first year of his age He was the son of John Irvine Bulloch, and great-grandson of Governor Archibald Bulloch, of Revolutionary fame He graduated from Yale College in 1835, and having selected medicine as his profession, at once entered upon his studies in the medical department of the University of Pennsylvania, from which he graduated in 1838 The thesis presented to the faculty on this occasion was on "Pneumonia"

After obtaining his degree he went to Europe to further prosecute his professional studies, the greater part of his time being spent in the hospitals of Paris He then returned to the United States, and settled in practice in his native city Being well prepared, and zealous in the performance of his professional duties, he soon acquired a large and growing practice, and throughout his life he retained the respect and confidence of the community and his professional brethren Being public-spirited, he associated with all the literary and benevolent societies of his city He was a member and earnest promoter of various medical organizations He was President of the Medical Association of Savannah, and also, at one time, of the Georgia State Medical Association He became a member of the American Medical Association in 1851

Dr Bulloch was one of the founders of the Savannah Medical College He was a surgeon in the Confederate army during the late civil war, was alderman of Savannah for two years, and was physician to the city gaol from 1877 to the time of his death His medical writings were chiefly confined to articles contributed to the *American Journal of the Medical Sciences*, and to the *Savannah Journal of Medicine* His remains were placed in Laurel Grove Cemetery, where the peculiar services of Masonry were performed in the presence of a very large concourse of his friends, and various associations of which he was a member

ASSOCIATION ITEMS

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with Five Dollars, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly Journal of the Association will be forwarded for one year

Richard J Dunglison, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

The Cholera in Europe —Thirty-five hundred and ten cases of cholera, and 1,342 deaths from the disease were reported throughout Spain on August 10

On August 10 there were fifteen cases entered at the Pharo Hospital in Marseilles, some of them being hopeless In that city "Bureaus of Aid" for night relief have been opened on account of the difficulty of obtaining medical assistance On August 11, there were thirty-nine deaths from cholera At a meeting of the municipal authorities on August 11 100,000 francs were appropriated for sanitary purposes The Chamber of Commerce has protested to the Government against the system of quarantine, and claims sanitary measures will be taken against vessels coming from Genoa, Naples, and other ports where deaths from cholera are suspected

It is quite certain that cholera has appeared in Toulon, two deaths having occured on August 10, and several other cases, without fatal results as yet, having occurred in the vicinity of that city

It has been reported that a fatal case of cholera has occurred in Bristol, England, but the report has not been authoritatively confirmed

Precautions Against Cholera in America — The Canadian Government have not sufficient proof yet of cholera being the cause of the death of the sailor at Bristol or of there being any case of cholera in England Should there be, however, the Government think the proclamations of June 17, 1885, and June 27 last will fully meet the case These proclamations provide for the quarantine of all vessels coming from infected ports The first provides that Grosse Isle, Lawler's and Partridge Isles, with such other places as may from time to time be thought fit, shall be used as places of quarantine, and that boats suspected of being capable of introducing cholera into Canada shall make quarantine until discharged by the authorities The second provides that all vessels coming from or having called at, on their voyage, any port of Spain or the Mediterranean Sea, or the port of London, in England, shall be subject to the quarantine regulations in force for the ports on the east coast of the Dominion Bristol, not being Spain, the Mediterranean Sea, or the port of London, would require either a straining of the terms of the proclamation or a separate proclamation

The quarantine officers at Baltimore and at the Delaware Breakwater have been notified to look out for three vessels which have sailed from Genoa for those places without proper bills of health

Dr John Ten Brook of Paris Edgar County, Illinois, one of the oldest practitioners in the State, died at his residence, on the 8th of August, 1885, aged 77 years Though leading a quiet unobtrusive life, he performed well all the duties of an active and intelligent practitioner of medicine, and of a good citizen, and has gone to his rest respected and honored by all who knew him

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 1 1885 TO AUGUST 7 1885

AN UNUSUAL CASE OF SUB-SEROUS FIBROUS TUMOR[1]

BY J F Y PAINE, M D

PROFESSOR OF MATERIA MEDICA, THERAPEUTICS HYGIENE AND CLINICAL MEDICINE MEDICAL DEPARTMENT UNIVERSITY OF LOUISIANA MEMBER OF THE TEXAS STATE MEDICAL SOCIETY ETC

It is not my intention, in the subjoined report, to disclose either a new therapeutic agent or an improved method of employing an old one, but simply to add a note to a procedure instituted by Hilderbrandt, and which already enjoys the sanction of our science Without attempting a *resume* of the literature of the subject, it is proper that I should state that the method has not met with universal favor, and it is partly for this reason that I venture to read the notes of a case of sub serous fibrous tumors lately under my treatment

Miss V E G, æt 43 years, native of Louisana, of good social position, school teacher Family history exceptionally clear Personal health uninterrupted until about two years preceding my first visit In the early part of 1882 the patient began to experience unaccustomed sensations, which soon developed into positive disorders, such as abdominal and pelvic pains, irritability of bladder and rectum, menorrhagia, leucorrhœa, etc It was not until the early part of 1883 that she discovered anything unusual in the contour of the abdomen The presence of two hard masses, one in the hypogastrium, and the other in the right inguinal region, excited her apprehension, and she consulted a physician From that period until January, 1884, the tumors had grown with such rapidity that the abdominal cavity seemed filled to its utmost capacity Not only were the viscera compressed and displaced, but the walls and integumentary tissues were so distended that she suffered almost constant pain Both her attending and consulting physicians are prominent practitioners in Galveston, and I have no doubt that their management of her case is above criticism A frank prognosis on their part, however, determined her to dismiss them, and employ other counsel It was at this juncture that I was called, and from which period my notes date

My first visit was made on January 27th, 1884, and I was impressed by the ex-sanguined face, anxious expression, rapid breathing, and feeble, unrhythmic pulse of my patient Examination revealed an enormously distended abdomen, with skin so tight that it could not be pinched, and a hard, uneven surface The uterus was decidedly retroverted, somewhat enlarged, and considerably below its normal plane There were unmistakable evidences that pressure was impeding the functions of the bladder, kidneys, intestines, stomach, lungs and heart Dyspnœa and irregular heart-action caused great distress The stomach was so compromised that only small quantities of food could be ingested, and even they were followed by various dyspeptic phenomena, the bowels were evacuated with difficulty, sleep was disturbed, pressure upon the sacral plexus gave rise to sciatica, which at times was agonizing The patient was confined to her room, and a considerable proportion of the time to her bed Exhausting menorrhagia occurred every month Measurements of the circumference of the trunk at the epigastric, umbilical and hypogastric regions yielded 50, 51 and 51½ inches respectively From that date, January 10th, to Feb 10th prox, there was an increase of ¼ inch for the first, ½ inch for the second, and ½ inch for the third region (adhering to the order in which they were first named)

On March 16th, thirty-five days after second and forty nine after first measurements, there was a decrease of 4¼ inches for the epigastric, 4½ for the umbilical and 5 for the hypogastric regions Amelioration of every symptom was marked Patient took more food, with less discomfort, slept better, was comparatively free from pain, menorrhagia was less pronounced, was able to take a moderate amount of outdoor exercise, and, barring occasional hysterical paroxysms, has made uninterrupted progress

April 1st, sixteen days since tape-line was last applied, shows a loss of 4 inches for the first, 4 for the second, and 3 for the third region, and patient much improved in every respect

May 21st, fifty days, reveals a decline of 10 inches for the first, 9 for the second, and 8 for the third region With the exception of a few small abscesses, resulting from hypodermic medication, patient expresses herself as feeling "quite well"

July 11th, fifty-one days, discloses a falling off of 5½ inches for the first, 4½ for the second and 4¾ for the third region Patient feels so well that she enters upon a general round of visiting, returning calls made while she was confined to her room On the 6th of October she resumed her occupation of teacher in the public schools in this city, and has only lost one day, and that on account of sore throat.

---

[1] Read in the Section of Obstetrics and Gynecology at the Thirty sixth Annual Meeting of the American Association

December 23d, ten months and twenty-seven days after my first treatment, measurements displayed a circumference of 24 inches against 50¼ for the epigastric, 30 against 51½ for the umbilical, and 30 instead of 52 for the hypogastric regions, exhibiting a difference of 26¼, 21½ and 22 inches respectively. As far as could be ascertained, every function of her economy was normal, including menstruation. Mensurations taken to day, April 18th, gave a still further slight decrement.

The treatment of this patient can be briefly stated. Ergot hypodermically was the only directly curative agent employed, but it was carried far beyond the limit advised by Hilderbrandt and others. I began with the daily use of the stereotyped dose of three grains of Squibbs' solid extract, diluted with a little glycerine and warm water, and so continued it for ten days, when my patient's increasing distress seemed to justify the administration of a like quantity morning and evening. From the eleventh day I increased the dose one grain each day, until ten grains were given morning and night. Slight signs of ergotism appearing, I did not increase the quantity further, but continued it in that degree until April 1st (fifty four days), when its evening exhibition was omitted. Ten grains daily at a single dose was maintained until May 21st (fifty-one days), when the great shrinkage of the tumors, and disappearance of painful symptoms, led me to extend the interval to every other day. This latter order was pursued until July 11 (fifty one days), from which date to Dec. 23d, the quantity employed was reduced to five grains, and the interval increased to three days. As previously stated, Squibbs' solid extract was the preparation selected, and the quantity used was freshly diluted with warm water at the time of using it. Less irritation was produced by fresh aqueous solutions than by others, however compounded, when allowed to stand a few days. The points of puncture were not restricted to any particular region, but a considerable extent of the surfaces of the trunk, upper and lower extremities were utilized first and last. The needle was variously introduced—obliquely into the subcutaneous areolar tissue, and straight down into the muscular structure—without appreciable difference in result as regards local irritation. Occasional abscesses developed in spite of every precaution.

None of the distressing symptoms of ergotism manifested themselves during the progress of the treatment. No gangrenous tendencies, no spasmodic complications, neither were there troublesome headache or vertigo. Nervous phenomena and nausea were the only symptoms which could be attributed to ergot. Hysterical paroxysms, however, had annoyed her from the beginning of her illness, and were no doubt in large measure due to exhaustion and reflex disturbance. The most notable effect of the ergot was slowing of the cardiac rhythm. The supplementary treatment consisted of blood, nerve and digestive tonics, rigid attention to all the functions, carefully selected diet, well regulated personal and house hygiene, and anodynes and hypnotics when indicated. I improvised an abdominal supporter, which the patient wore when she sat up or walked, and it afforded great relief to the pelvic viscera.

The patient visited the Exposition at New Orleans in the former part of January, during a very cold spell, and the combined influence of fatigue and chilliness gave a fresh impetus to the tumors, but within a month, under the same line of treatment already detailed, they had degenerated into insignificant, hardish masses. Five grains every four days is still employed. It cannot be urged that the rapid retrogression of these tumors is anywise the result of senile involution connected with the climacteric, for the patient had never suffered the slightest aberration of the menstrual function until menorrhagia was excited by these abnormal growths.

Galveston, Texas, April 20th, 1885.

AUTOPLASTY, THE CONSERVATIVE SPIRIT OF MODERN SURGERY[1]

BY F. FORMENTO, M.D.,

OF NEW ORLEANS, LA.

The progress made in the science of medicine and surgery since the commencement of the present century has been wonderful indeed. The spirit of positivism and experimentation which characterizes our epoch, the generalization of clinical and practical studies, the great modern wars which have afforded such vast fields of observation, the most thorough knowledge of anatomy and physiology, and the immense improvement made in the physical and chemical sciences, satisfactorily explain the true and permanent advancement of medicine and surgery. Every day chemistry furnishes us with precise methods and new discoveries. The most wonderful and valuable of all has certainly been the discovery and generalization of anæsthesia, general and local, and particularly ether and chloroform, and the newly discovered cocaine. These extraordinary agents, which have abolished pain, have permitted operations, such as ovariotomy, gastrotomy, the removal of internal tumors, and extensive autoplastic operations for restoration or creation of organs, which, without anæsthesia, would never have been dreamed of.

Mechanics also offers to surgery new and valuable resources, incessantly inventing and improvising instruments, apparatus, and physical appliances of all kinds. The use of India rubber, of solidified substances, such as plaster of Paris and silicate of potash, the introduction of metallic sutures and of the ecraseur, the application of the resources of optics and acoustics, which allow us to see and hear into the depths of organs, and finally, the application of electricity and galvano-caustic, are as many *innovations*, every one of which has marked an epoch of progress and advancement in science. Thanks to the means and resources we now possess, is it surprising that

---

[1] Read in the Section on Surgery and Anatomy at the Thirty Sixth Annual Meeting of the American Medical Association.

Surgery should become more and more *conservative*, that it should tend towards easing without mutilation? The amputation of a limb, not less than the extraction of a tooth, is now looked upon as a last resource, a painful acknowledgment of impotency. The tendency is to save, to preserve. Unfortunately, there will always remain a great number of cases, in which the only resource will be the sacrifice of a limb or organ. Fortunate, in many instances, if we can save life at the cost of a mutilation!

The surgeon of to-day is certainly less inclined to cut, less inclined to heroic treatment, than formerly. Now science has progressed, and we have at our command means which our predecessors did not possess. Resections are being in many cases substituted for amputations, compression for ligation in the treatment of aneurism, the use of water, cold or hot, has in many cases, in ophthalmic and gynecologic practice, advantageously taken the place of caustics and irritants. More advanced hygiene, a better understood régime, surgical drainage and antiseptic dressings, the use of disinfectants and germicides, all these combine to enable us, in many cases, to save life without running the risks of dangerous surgical operations.

The word autoplasty, or aroplasty, as preferred by Velpeau, is from a Greek word, signifying literally to reconstruct, to mould. Autoplasty constitutes certainly one of the greatest triumphs of modern conservative surgery, for the autoplasty of the former ages applied only to the repair of the nose, as we shall see later, while it nowadays has created a special department of operative surgery. The perfection which plastic surgery, says Prof. Gross, has attained within the last twenty-five years is truly wonderful, and affords a striking evidence of the ingenuity, talent, and enterprise of the medical profession in different parts of the world. It has literally been a field of conquest, upon which have been achieved some of the proudest triumphs of the human mind in modern times. Like many other useful discoveries or applications of science, it has passed through succeeding periods of enthusiasm, indifference, and quasi oblivion, until modern surgery has once more revived it and placed it on sound, philosophical, scientific principles.

Autoplasty proper is the art of restoring losses of substances or deformities caused by disease or injury, by means of tissue taken from the affected person itself. In a more extended sense, it may be said to be the art of organic restoration, including the attempts which have been made—successfully at times—to preserve organs partially or totally separated from the body, and the still more wonderful, but less authenticated, facts of separation or restoration of organs made by means of organic living material taken from another individual, man or animal. If so understood, the domain of autoplasty could be stretched very far and one can readily understand to what humoristic and grotesque conclusions the consideration of the subject might lead. In this connection many facts, or so called facts, might be here related which belong more properly to fiction and novel than reality. Many are familiar with the amusing story of Edmond About, entitled "A Notary's Nose." That story may not have been, after all, a pure invention of M. About, if we are to believe certain stories told by travellers in India, who assert that in that country the manufacturers of noses often employ the skin of the buttocks of slaves for the making of noses for grand personages who have had the misfortune to lose, judicially or otherwise, their olfactory organs. We know that cutting off the nose is a legal punishment often imposed in some of the countries of India. Dutrochet, among others, describes minutely the *modus operandi*. The nasal surgeon begins by beating well the region which is to furnish the needed material with a sort of cat-o'-nine-tails, in order to increase the suppleness and vascularity. He then cuts out a thick piece of skin, of proper size and shape, and secures it by means of sutures to the previously denuded borders of the stump. When once prepared he carves out of that region a thick piece of skin of proper size and shape, and secures it by means of proper sutures to the borders of the remaining part of the nose, which has been previously well denuded.

I do not guarantee the authenticity of those various plastic operations, which, no doubt, are to be accepted *cum grano salis*. I may say, however, that, considering the question in its purely anatomical and physiological aspect, the fact of restoration of organs in an individual by skin-grafting from another individual of the same race and species is not inadmissible, especially if connection between the two is not severed until the borrowed tissues have contracted adhesion with the region borrowing them. Reliable authorities give examples of still more extraordinary plastic adhesions. Science possesses many observations of complexed organs, of some considerable volume, such as a nose, a lip, a part of the chin, the end of a finger, which, after being entirely separated from the body, were reapplied, properly secured, and engrafted perfectly well. We read in Boyer that, in a paroxysm of anger, a woman bites off the nose-end of her husband and spits it on the ground. A surgeon, who happens to pass by, picks it up, and, after washing it, applies it and sutures it with care. The nose end united perfectly. In Heidelberg, where duels with the broadsword used to be, and are still, the order of the day among students, ablations of noses are quite frequent. Chelius reports several such cases in which he obtained perfect reunion of noses that had been cut off by the broadsword, and Dr. Hoffacker, the official surgeon of those students' duels, has related in the surgical annals of that University sixteen well authenticated facts of the kind.

The knowledge of the phenomena of cicatrization of wounds and injuries, and of the repairing of losses of substance which take place under our daily clinical observation, gives a satisfactory explanation of the phenomena of autoplasty. The margins of a wound made by a cutting instrument, if placed in juxtaposition, will adhere and unite together completely. The skin of any region of the body, if properly denuded, will unite intimately with that of any other region. These reunions and adhesions are due to effusion of plastic lymph, which becomes vascular and soon establishes a community of circulation between the parts Why could not these adhesions take place between individuals of the same species? Do they not happen at times in the pregnant womb? Do we not sometimes see twins united by fusion of organs, or by simple integumentary adhesions?

Experiments made on living animals confirm and enlighten the teachings of the clinique Odin, of Lyons, was the first to obtain true animal graftings You know of his interesting studies on the periosteum, and of his remarkable sub-periosteal operations Among other experiments, he implanted pieces of periosteum, tails of rats, etc , in the crests of roosters, and saw them take root and develop

We all know that skin grafting in the cicatrization of extensive burns and injuries is daily practised, and gives excellent results

Autoplasty had undoubtedly its origin in India, where it has been practised from time immemorial The barbarous custom of the judicial amputation of noses, above referred to, must have given rise to the art of making noses, or rhinoplasty, which was most likely the first plastic operation performed on man It seems that the number of mutilated noses soon became so great as to give rise to a new industry, and created a special class of practitioners, that of the nasifer Certain Indian tribes, the Kumas, whose fame has reached our days, displayed wonderful talent in the art of rhinoplasty They invented the Indian method, which takes the necessary flaps from the tissues surrounding the loss of substance, twisting the pedicles to better adapt them *in situ*—autoplasty by torsion

The Bianca family, of Sicily, father and sons, were the first to perform rhinoplasty in Europe It was Tagliacozzi, an Italian surgeon, who indicated the scientific principle of this new operation He operated many times himself, and created the Italian method, which takes the necessary tissue for reparation of losses of substance from distant regions—for instance, from the anterior part of the arm in rhinoplasty The first successful plastic operation in Europe attained universal applause and admiration, and procured to Tagliacozzi the honor of having his statue erected in the Anatomical Amphitheatre of Bologna Notwithstanding these successes, which, at times, seems inherent to all new discoveries, autoplasty soon fell into disuse and oblivion, and was condemned by most authors until the year 1815, at which time it was revived, and once more put in vogue, by Caspai, of London Since that time, Dupuytren, Lisfranc, Blondin, Jobert, Liston, Grafe, and Dieffenbach, in Europe, and Pancoast, Warren, Prince and Buck, of this country, have published their successful cases, and introduced in the operative procedure many useful modifications Let us here mention an extraordinary example of courage and perseverance of both patient and surgeon Roan, of Paris, is said to have performed fifteen distinct plastic operations on the same patient, for remedying an awful deformity It is hardly necessary to add that the patient was a young woman

The above named surgeons were the inventors of the procedure *par glissement*, or French method, which dissects the needed flaps from the environing region, and causes them to *slide* and spread, without torsion, so as to cover the loss of substance

Autoplasty applies especially to the repairing of noses, lips, cheeks, ears and eyelids, to vicious cicatrices, to the keeping open of natural orifices which tend to obliterate and closing certain pathological openings, such as fistulæ, etc

The first conditions of success are that the subject be young and healthy, that the plastic flaps be taken from a sound vascular region, that they may be of a certain thickness and well nourished, in order that they may retain proper circulation and innervation with the parts furnishing them, that these flaps be neither too large or too narrow, and that the parts which are to be united be previously properly denuded, and then kept in exact contact by their bleeding surfaces The great danger in the operation is sloughing or mortification of the flaps, which the above-enumerated conditions are intended to prevent As to the results of the operation, they are generally useful, and at times most satisfactory and remarkable, as in the two following cases

A few years ago I was consulted by Miss Corinne M , aged 18 years, from Attakapas She was suffering from a deformity of the face, which caused her excessive mental suffering and made her life a burden to her I heard from her parents that when she was 8 or 9 years old, the child was affected with some kind of terrible fever, during which gangrenosis had supervened, and in spite of all treatment had produced the monstrous deformity for which they now claimed the resources of the surgeon The whole of the left cheek, together with two-thirds of the lower lip, had been entirely destroyed by the sloughing process, and had entirely disappeared, the left commissure of the upper lip was drawn up obliquely by adhesions Instead of the soft tissues of cheek and lip covering the maxilla bones, there existed a deep hollow, nothing but fibrous adhesion and cicatricial tissue covering the surface of the two left maxilla, there had been, evidently, in several spots and especially along the alveolar processes destruction and loss of osseous substance, dense fibrous adhesions existed between the two maxilla bones, which prevented their separation, so that what remained of the mouth could be opened scarcely wide enough to admit the end of the finger, all the teeth had not been destroyed, there were eight of them still firmly implanted in the alveolar ridge, they were of extraordinary size and shape, and projected almost horizontally, resembling the tusks of a wild boar Food reduced to pulp had to be introduced in the mouth with the fingers, in the spaces existing between the teeth, there was scarcely a perceptible lowering of the chin in the act of mastication, which was accomplished with difficulty by simple lateral or side motion There was naturally great trouble in sucking, drinking, swallowing, and articulation of sounds, the voice was deep, hollow and hoarse, and her speech could only be heard with difficulty The poor girl habitually wrote on a slate to convey her thoughts

The right side of her face presented a striking contrast with the afflicted side, the right cheek being round, firm, and of beautiful complexion The eyes were lovely and intelligent, the head well shaped and covered with an abundant growth of beautiful black hair The general health was excellent, and with the exception of that horrible deformity the patient presented all the appearance of robust health, of medium size, fair and plump After having minutely and repeatedly examined and studied the multiple lesions just described, after some hesitation, quite natural under the circumstances, I explained to the family and to the young girl the dangers and difficulties of the long and difficult operation, which alone might possibly correct such a deformity, and for which I could find no precedent in surgical works Without disguising any of the obstacles we had to encounter, I held up to the imagination of the poor victim the brilliant prospect of a complete success She was willing and anxious to take the risk of an operation

A few days after, on the 22d of March, 1871, with the assistance of my friends, Drs Trudeau, Sauvé, Taney, and Castellanos, and in presence of several friends of the family, I proceeded to perform the following operation of autoplasty *par glissement*, which, after complete anæsthesia with chloroform, consisted 1st, In extracting the projecting teeth, 2d, In detaching and dissecting the remaining tissue around the gap produced by such loss of substance, upwards nearly to the lower orbital wall, forward to the nasal bone, and backward to the left ear The fibrous adhesions which united the two maxillary bones, as well as the margin itself, or border of the alveolar process, in both maxillary bones, were carefully removed, detached, or scraped, by the bistouri gouge and chisel, so that the two maxilla could now be well separated, the tempora maxillary articulation being intact

The complete detachment or dissection of tissues above, forward, and backward, would have scarcely covered one-third of the ugly gap My main reliance was in the formation of a thick, well nourished flap, well quilted with adipose and cellular tissue, cut out of the left antero lateral region of the neck In making that flap, dissection was carried downwards to two inches from the clavicle What remained of the lower lip, a small ball of flesh of the size of an egg hanging over the chin was utilized to best advantage, its mucous surface, which was greatly in excess over the cutaneous, was used as a buccal border to be accurately stitched to part of the upper border of the lower or neck flap It was only after having ascertained by repeated trials and measurements that there was sufficient tissue to cover abundantly the gap in the face, that all these flaps were brought together, but not before all hæmorrhage had ceased This was of a trifling nature, no large vessels having been cut during the operation

Sutures with silver thread and fine silk were applied with extreme care, not less than fifty stitches being necessary to accurately close the large *hiatus* The operation, including the suture and dressing, lasted two hours and twenty minutes In autoplastic operations, under chloroform especially, the precept "*Cito*" finds no application We should above all proceed slowly and unhurriedly, with geometrical precision It is a delicate operation, which has particularly but justly been compared to miniature painting, it must be well *finished*

For eight days the head was kept inclined forwards by means of a special cap and bandage, the patient being watched day and night to avoid all movement, all drawing on the flaps No local application except compresses dipped in cold water Milk diet No untoward complications supervened The threads and sutures were gradually removed between the eighth and fifteenth days On the fifteenth day she got out of bed The results surpassed by far our most sanguine expectations Miss M C now had a human face Perfect reunion had taken place in all the lines of cicatrization One single sitting, one operation had been sufficient to obtain a most wonderful result, while at times ten and fifteen plastic operations have been necessary for a satisfactory result

A month after the operation the patient returned to her home in Attakapas, scarcely recognizable to her best friends Six months after she wrote to me "I am perfectly happy I can eat, drink, speak and sing as well as anybody, and I am soon to be married " Miss M C is to day living at Port Brown, a happy wife and mother She has certainly well deserved her happiness

My second case is less complicated It is simply a case of rhinoplasty It was performed a few weeks ago in New Orleans, with the assistance of Drs Ayres and Underhill Mrs B, living in the third district, was one of the many victims of a quack, or cancer doctor, living in that part of the city She consulted him very foolishly, as some even more enlightened and aristocratic people will often do, for a small pimple, a trifling one, probably, on her nose She was, at the time, and is to day a splendid specimen of health and vigor, the mother of several fine, healthy children Her pimple, she says, was of the size of a small pea, and caused no pain, it did not bleed, only it was annoying to her Some unknown violent caustic was injudiciously applied to it, and the result was that a few days after, when the eschar fell off, there remained a hole in the middle of the nose sufficiently large to admit the first phalanx of my thumb, the skin, cartilage and part of nasal bones had been destroyed, and the tip of the nose, unsupported above, was perfectly loose and movable in any direction The Schneiderian membrane was highly inflamed in spite of the patients efforts to protect it from wind and dust The sense of smell was entirely lost Such was her condition when she came to me a year after the cauterization With the exception of the root of the nose, which was covered with cicatricial tissue extending towards the forehead, the adjoining tissues were healthy, the cheeks full and plump In deciding upon the mode of operation, we concluded to make two thick lateral flaps from the cheeks to bridge over the large opening, operation *par glissement* The patient being completely under the influence of chloroform, the borders around the loss of substance, particularly the loose extremity of the nose, were well denuded, and two thick, well-nourished lateral flaps, one inch and a half long, and of the width of the hiatus, were dissected from the cheek on both sides Two small arteries were twisted, and the flaps were accurately drawn over and applied to each other, in the median line, and to the denuded tissues above and below Fourteen silver sutures were used Reunion by first intention took place, and the result of the operation was perfect

I should here remark that the climate of Louisiana is most favorable to the success of autoplastic operations, and to surgical operations in general We but very seldom have here erysipelas, gangrene, or pyæmia following the most serious operation, and union by first intention, after amputation of limbs or of the breast, with or without antiseptic dressings, are far from being unfrequent I have had several cases in my own practice Our climate has some analogy with that of Lower Egypt where operations are remarkably successful A warm, damp atmosphere, resembling that of a hot-house, is favorable to vegetation Why should it not be so to animal growth, to cicatrization, to repairing of tissue?

Louisiana now boasts of comparatively the largest number of Cæsarean operations, and when the results of the ovariotomies, performed in this State, will have been published, they will be found to compare favorably with the most favorable of any other country in Europe or America

PENETRATING PISTOL-SHOT WOUND OF ABDOMEN —LAPAROTOMY—SUTURE OF INTESTINES— PELVIC HEMATOMA—RECOVERY

BY JOHN B HAMILTON, M D,

SUPERVISING SURGEON GENERAL U S MARINE HOSPITAL SERVICE
PROFESSOR OF SURGERY UNIVERSITY OF GEORGETOWN, ETC

Notwithstanding the manifest soundness of the arguments in favor of operative interference in case of penetrating wounds of the abdomen, the weight of modern authority as indicated in the surgical text books is still against it, and it is only by the reports of cases where an actual test is made upon the human subject that the truth will ultimately prevail The careful and conscientious experiments of Parkes upon dogs, while carrying conviction to the minds of many, are yet met by the masses with the objection so quaintly urged by Turner,[1] that "the comparative anatomy is not a sufficient foundation for us to go upon, in taking experiments thence, cat's guts and man's being so widely different in their texture We have many instances of these parts wounded in brute creatures, and after sewing up again, they have been let go to lick themselves whole on the outside, while nature is playing the surgeon within Nay, Dr Musgrove acquaints us that he took out the coecum of a bitch, carefully tying up the vessels and stitching up the divided parts, when in three weeks time she seemed as well as ever"

To the case recently reported by Dr Bull, of New York, I now add the following

J W Wood, a mulatto, æt 19, a waiter at the Tremont House in this city, was accidentally shot by a pistol carrying a 32 calibre ball The wound was received at 2 10 P M, and he was taken to the Providence Hospital There was considerable shock I examined him at 4 20 P M and found that the missile had entered the skin about an inch to the right, and an inch above the navel A flexible Nelaton probe following the track of the ball passed downward and inward under the rectus muscle and entered the abdominal cavity The probe was withdrawn and the patient etherized There were present Surgeon J C McKee, U S Army Surgeon G W Stoner, Marine Hospital service, and Dr D P Hickling, the House physician The belly having been shaved, and washed with solution of bichloride mercury, an incision was made in the linea alba about six inches long, the peritoneum raised and incised A spurting artery was seen in the mesentery, and the abdominal cavity was full of blood The artery was immediately tied with a fine catgut ligature, the intestines drawn out loop by loop, and the wounds stitched with Lembert's suture as fast as they could be reached Eleven wounds requiring suture were found in the small intestine, and two in the ascending colon The wounds varied in size from a mere nick in the wall of the intestine, to those where the ball had passed directly through it, and all were everted, the mucus surface pointing out

There was no fæcal extravasation, doubtless owing to the fact that less than two hours had elapsed from the time of receipt of the injury, but a canteloupe seed was seen and removed from the mesentery The omentum was cut by the ball in several places, and as it was difficult to stop the oozing, a ligature was placed around the wounded mass and it was cut off All sutures and ligatures used were the finest size of carbolized catgut The abdominal cavity was then sponged with solution of bichloride of mercury, cleaned and dried, and the incision carefully closed with deep sutures of silver wire and superficial ones of silk Narrow strips of adhesive plaster were then placed across the incision about an inch apart, a square of sublimated gauze laid upon it, and iodoform dusted over the gauze and the surface round about A broad flannel bandage was then placed snugly over the abdomen, the patient placed in bed, and as there was still some shock from the combined effects of the anæsthetic and the wound, he was surrounded with bottles of hot water Reaction took place shortly, and he was given 06 gm of opium every three hours

Sunday, July 12, 8 A M —Temperature 100 2° F, pulse 112, respiration 20 6 P M, temp 100 8, pulse 130, resp 24 General condition good, and had slept several hours during the day Diet confined to beef tea

Monday, July 13, 8 A M —Temp 101 6, pulse 112, resp 20 Patient restless, complained of pain in wound, and in right testicle There was *much* tenesmus, and a gentle effort was made to administer an enema, but the small quantity of water thrown in was without effect The frequency of the opium was then increased to 06 gm every two hours The abdomen was moderately distended A lotion of lead and opium was applied to the painful testicle

---

[1] Turner Daniel "The Art of Surgery" London 1741 Vol II

Tuesday, July 14, 8 A M—Temp 101 4, pulse 112, resp 20, 6 P M, temp 100 8, pulse 112, resp 20 The distension of abdomen increased The patient was very restless, and complained of a throbbing pain in the wound A rubber water coil was applied during the day, and at 6 30 P M the lower portion of the wound was re opened, and by suction with a syringe it was sought to ascertain whether pus was present or not None was found, and after injecting the wound with the mercuric solution, it was again drawn together The opium was then increased to 06 gm every hour Tympanites troublesome

Wednesday July 15, 8 A M—Temp 101, pulse 104, resp 16 Patient slept some during the night, but very restless Tympanites still a source of great discomfort 6 P M, temperature 103, pulse 124, resp 28 Ether administered for the purpose of giving an enema, some fæcal matter came away The opium was then reduced to 06 gm every three hours, and sherry wine every four hours A flaxseed meal poultice was applied to the scrotum

Thursday, July 16, 8 A M—Temp 100 5, pulse 112, resp 28 Patient had several stools during the night, had slept but little, was uneasy and the tympanites great At 6 P M temperature 101 2, pulse 112, respiration 16

Friday, July 17, 8 A M—Temp 98 4, pulse 128, resp 24 The patient had several stools during the night, which were exhausting and painful To check the diarrhœal tendency gave

Quiniæ sulph /90
Tr kino
Syr rhei aromat āā 16/

M et sig—Teaspoonful every 3 hours Chicken broth substituted for beef tea

6 P M—Temp 101 5, pulse 112, resp 32 The tympanitis still great, and a rectal tube was introduced, without result

℞ Ol terebinth, 8/
Mucilaginis acaciæ 64/

M et sig—A teaspoonful every 4 hours Opium discontinued

Saturday, July 18, 8 A M—Temp 101 2, pulse 112, resp 24 Had five stools during the night, and the abdomen was quite free from tympanites 5 30 P M—The patient had a convulsion lasting five minutes, and as there had been no operation from the bowels during the day the astringent mixture was stopped Two silver sutures were removed and several silk ones An exploring needle was introduced into the painful and swollen scrotum without result 6 P M—Temp 101, pulse 112, resp 24

Sunday, July 19, 8 A M—Temp 100 6, pulse 112, resp 24 Exploring needle again introduced into the scrotum without result, and at 2 P M six leeches applied Milk and lime water added to diet, and as the diarrhœa had again set in, the astringent mixture was renewed 6 P M—Temp 100 8, pulse 100, resp 40

Monday, July 20, 8 A M—Temp 100 2, pulse 100, resp 24 No stool during night, but large quantities of flatus passed The testicle still painful, fluctuation present, incision made, pus to the amount of 10 ounces evacuated, and the cavity washed out with the compound solution of bromine At noon the patient was cold, and extremities bathed in clammy perspiration He was sponged with hot mustard water At 4 30 P M, one small stool was passed, containing two lumbricoid worms 6 P M—Temp 100, pulse 100, resp 28 At midnight, the coolness of extremities continuing, whisky 16 gm was given every hour

Tuesday, July 21, 8 A M—Temp 99 8, pulse 92, resp 28 Whisky stopped at 9 A M 4 P M—The patient had epistaxis 6 P M—Temp 100, pulse 104, resp 24

Wednesday, July 22, 8 A M—Temp 99 6, pulse 90, resp 24 6 P M—Temp 100 2, pulse 100, respiration 24

Thursday, July 23, 8 A M—Temp 99 6, pulse 88, resp 24 Tongue furred Ordered quininæ sulph 24 gm three times daily At 5 P M, Dr Hickling found the patient in great tenesmus, requiring bedpan constantly, only mucus passed the rectum, and an enema was ordered which returned about four ounces at a time At 10 P M, the tenesmus again coming on, the doctor made an examination and discovered a large tumor in the rectum pressing on the rectum A hypodermic injection of morphia was given and the patient slept four hours, after which the pain returned, and while on the bedpan he passed the bullet

Friday, July 24, 8 A M—Temp 99 8, pulse 88, resp 20 The patient's general condition was very good I examined the tumor through the rectum and found it to be a pelvic hematoma As the tumor seemed quite solid at its upper portion, I felt quite confident that nothing but its breaking down, would relieve the violent and almost constant tenesmus, so I passed a narrow bladed knife through the rectum in the median line, about two inches within the anus, directly into the tumor There gushed out at once about a pint and a half of thin badly smelling blood, and as the patient seemed so weak I did not complete the operation by passing an instrument into the puncture and breaking down the clot In a few minutes another fit of tenesmus came on, during which about the same quantity of badly smelling blood came out through the puncture, and I became anxious to control its flow as the patient was almost in syncope, a plug of lint was inserted in the rectum above the puncture, and the portion below filled with ice Hypodermic injections of whisky with ammonia were administered Hot beef tea given by the mouth, hot bottles placed around him, and the foot of the bed elevated He revived and commenced to improve

Saturday, July 25, 8 A M—Temp 101, pulse 112, resp 28 Patient still weak, the plug was removed from the rectum Beef tea with milk punch every two hours 6 P M—Temp 100, pulse 112, resp 24.

Sunday, July 26, 8 A M—Temp 99 8, pulse 104, resp 28 Passed a small amount of fæces during the night The tumor could still be felt through the rectum, but only about one-third the original size

From this time on the patient steadily progressed toward recovery On the 1st of August the hematoma had entirely disappeared, and he was discharged well on the 8th of August, and on that day went by rail to his home, near Charlottesville, Va

The record of this case, kept so accurately by Dr Hickling, I have transcribed at the risk of being tedious, but I do so that one may be impressed with the incalculable care and patience required to successfully treat these cases The conclusion of the operation was, as will be seen, by no means the end of the anxiety In regard to the passage of the bullet, I had observed when sewing up the last wound in the colon that there was no counter opening, and as I could find no abrasion of the pelvic wall, nor of the iliac fossæ, I was forced to the conclusion that the bullet had remained in the bowel, I therefore gave orders that all fecal discharges should be carefully examined, which was systematically done from the time of the first discharge until the passage of the bullet

As the patient's recovery prevented an actual observation of the cause of the hematoma, I can, of course, only offer a conjecture, and that is that oozing continued from the mesentery, there was a large nick chipped out of the connective tissue next the small intestine in one place, which as the ball did not penetrate the intestine nor rupture an artery, I did not think it worth while to tie in mass I now think the spot should have been touched with caustic or some styptic The actual cautery could not have been used on account of the danger of penetrating the intestine Had this cut received attention, it is possible that the pelvic hematoma with its attendant complications might have been avoided This latter complication is scarcely mentioned in the surgical works, certainly not in connection with wounds of this character Pelvic hematoma in the female, on the contrary, has a quite extensive literature, but I have not seen it prominently mentioned that its most aggravating feature is the pressure on the rectum accompanying it It is not easy to thoroughly clean the abdominal cavity, where there has been considerable hemorrhage the surface of the bowels will be found smeared with blood, and the "toilet of the peritoneum" cannot be made with such perfection as it is possible to attain in ovariotomy, so that it is doubtful if the coming statistics of the operation will prove as favorable as in ovariotomy, but even with that disadvantage they will be vastly superior to the statistics of the wounds without operation

LITERATURE

The following opinions are interesting

"But if the great intestines be wounded, and the excrements discharge that way, it may be reasonable to lay open the wound and stitch the gut with the glover's stitch, sprinkling it with some of the aforesaid agglutinatives, and, reducing it back, stitch up the external wound of the belly, as hath been said "—*Wiseman* [1]

"But the question may be asked here whether a surgeon may not prudently, in this case, enlarge the wound of the abdomen, that he may be able to discover the injured intestine, and treat it in a proper manner Truly I can see no objection to this practice, especially if we consider that upon the neglect of it certain death will follow, and that we are encouraged to make trial of it by the successes of others Scacherus,[1] in Programmati Publica, Leipsig, ed 1720, mentions a surgeon who performed this operation successfully "—*Heister* [2]

"With very few exceptions, bullet wounds into the abdominal cavity are fatal It may be a question worthy of serious thought, in view of the hopelessness of our present practice, whether we ought not to cut boldly into the abdominal cavity, wash out the filth, and, bringing the wounded intestines to the surface, endeavor to produce an artificial anus "—*Andrews* [3]

"In examining the external wound, when no protrusion exists, should we find an escape of fecal matter—which proves that the bowel has been perforated—the abdominal wound must be enlarged, and the wound in the intestine closed by suture This is the only expedient for saving life, for if the contents of the bowel are allowed to escape into the peritoneal cavity, a fatal issue must be expected "—*Chisholm* [4]

"Already interference contrasts favorably with the do nothing system Reflection upon the results of ovariotomy, upon the results of gastroraphy and enteroraphy, applied to protruded wounded viscera, leads unavoidably, in the writer's opinion, to a conviction of the propriety of incising the abdominal wall when necessary in order to expose and sew up the wounded gut concealed within the cavity, whether divided by a cutting instrument or shot The obstacles to success are obvious, but it is a mortal peril which demands an extreme remedy "—*Otis* [5]

"I have the deepest conviction that there is *no more danger* of a man's dying of a gunshot or other wound of the peritoneal cavity, properly treated, than there is of a woman's dying of an ovariotomy, properly performed And, by the application of the same rules that guide us in ovariotomy to the treatment of gunshot wounds penetrating the abdominal cavity, there is every certainty of attaining the same success in these that we now boast of in ovariotomy "—*J Marion Sims* [6]

"When any of these conditions are present, the duty of the surgeon is clearly to enlarge the opening in the abdominal wall, or to make a new one in a more favorable location, sufficiently to admit of examination of the viscera in the track of the wound, to detect and ligate bleeding vessels, to suture intestinal rents, and to thoroughly cleanse the peritoneal cavity of extravasated matters "—*Pilcher* [7]

"Primary abdominal section in the mid line, gives the best command over the damage done, and furnishes the most feasible opening through which the proper surgical treatment of such damage can be instituted Further, its adoption adds but little, if anything, to the peril of the injury "—*Parkes* [8]

"I desire now to call attention to the fact that operative interference for gunshot wounds of the abdomen has been put to a practical test, and that it has been successful, and I hope that other members of this society may share my conviction that this plan of active treatment is now justified by these two successful cases, and that it should be adopted (within proper limits), to the exclusion of the 'let alone policy ' "—*Bull* [9]

RUPTURE OF THE SPLEEN FROM A PHLEBOLITE, WITH CONSEQUENT DEATH.—UTERUS UNICORNIS.[1]

BY CHARLES F. DARNALL, M.D.,
OF WALNUT, IOWA.

The subject of pathology being especially important to the physician, I take pleasure in contributing a mite to our accumulation of knowledge upon that topic, and it is done with the confession that wherever the writer has been wrong in his deductions and conclusions, it is for the reason that he has followed a rather obscure path, and not from the fact that the approval of others has been the incentive.

My subject, as indicated above, is the result of a *post mortem* examination, and the conditions therein existing were so new, that they have been investigated and formulated with the belief that the presentation will excite at least a momentary interest.

I was called on the morning of January 30, 1885, to see a German woman, æt. 36, VI-para, who had been attacked at four o'clock that morning with sudden pain in the bowels, followed by shock and syncope. The pulse was 120, temperature 96° F., and respiration 30, with prolonged expiratory efforts and much general suffering. There was no history of malaria, typhus or typhoid fevers, or any of the dyscrasiæ, nor of rheumatism or disease of the muscles or joints. She had never experienced any pulmonary or hepatic trouble, her nervous system had always been supposed to be in good condition, her menstrual periods easy and regular, without any ovarian or uterine difficulty. She had always occasional attacks of indigestion, unaccompanied with much pain, and her bowels were usually in a constipated condition. Her principal cause of sickness was in her kidneys, and her physician had treated her for "Bright's disease" a few months before her death. She was confined to her bed for several weeks with the supposed albuminuria, and only partially recovered. From her subsequent symptoms it is to be conjectured that she was afflicted with acute idiopathic cystitis. For a few weeks previous to the time when she was first seen, her physician, in treating her for her constipation, exhibited jalap, rhubarb, and other drastics, meeting with no success, as their effect was unable to correct her condition.

When she was first seen by the writer there was pain on pressure over the spleen and also in the right iliac region, and the omentum gave on palpation a peculiar brawny sensation, with no tympanitis or peritonitis. No absolute diagnosis being made other than that of a possible perforation of the bowel, an enema was ordered, with alcohol, quinine, and opium, hot poultices to the abdomen and dry heat to the extremities. Reaction did not follow, and death ensued on the morning of Feb. 2, three days afterwards.

Twelve hours later a *post-mortem* examination was held. The intestines were found empty, congested, and distended with gas. The omentum was injected, dry, and œdematous, with little serum or blood being present in the peritoneal cavity. The first thing that came to our notice was the half-filled bladder, the whole tissue of which seemed injected and hyperæmic. The uterus was found prolapsed, and the right ovary as large as a hen's egg, while the fimbriated extremity of the Fallopian tube was of a black, gangrenous condition, enlarged and infiltrated. The entire broad ligament was congested up to its attachment to the uterus. The ovary was opened, and discovered to be in a state of cystic degeneration, filled with clear albuminous liquid. Search was made for the left ovary, but it was entirely missing, as was also the round ligament, ovarian ligament, and usual blood-vessels, forming the anomaly known as *uterus unicornis*. The unilateral development characteristic of this rare condition of the uterus so far as the fundus pointing toward that side in which the ovary was present, was obliterated, being found in its highest state of perfection in the virgin, and as this woman had given birth to a child a few months before, the body of the uterus seemed not to have yet returned to that period of involution when this feature would be especially prominent.

The broad ligament was present, and between its folds was found the organ of Rosenmuller. As menstruation had taken place three weeks before death, the remaining ovary was further examined. A portion of it was found to be of normal tissue, full of Graafian vesicles, and *corpora lutea* in various stages of development and disappearance. The latter were of different sizes, lined with the duplicature of yellow granules of fat, and in the centre of one or two were blood clots. Surrounding them the tissue was of the natural type—not congested—and extended over upon the sides of the main cyst, showing it had sprung from one of them, and was of recent growth. Externally the walls of this cyst were of a white fibrous nature, internally of the peculiar bluish color common to ovarian tumors. The degeneration being multilocular, several very small cysts were in the parenchyma of the ovary, adjacent to the largest cyst, all filled with brownish or straw-colored liquids.

Proceeding in the search for the cause of death, the stomach was found to be in a rather congested state, the liver dark colored with spots of atrophy or contraction, and the kidneys injected, enlarged, and flabby. The spleen was atrophied, and upon the external surface near the superior edge we discovered a rent or laceration, large enough to admit the finger, from which exuded a small quantity of clotted blood. The solution of continuity was transverse to the length of the spleen, about two centimetres long, and in depth nearly three centimetres. Upon the internal surface was found what appeared to be a spot of fatty degeneration, as large as a silver dollar, covered by a tough yellow covered serous membrane, which being opened gave vent to a discharge of lymph or detritus. The bottom of the laceration was contiguous to this diseased spot, there being only about a centimetre of tissue intervening. In making this cursory examination of the abdominal viscera, a glimpse was caught of a foreign substance laying among the folds of intestine, and our next discovery was this same body in Douglas's fossa, whence it had gravitated during our manipulations

[1] Read before the Iowa State Medical Society at Cedar Rapids, May 20, 1885.

This was of a hard nature like a renal calculus, nearly the size of a horse bean, curved on the flat, rough, no facets, and in weight about one gramme.

Naturally we linked together this concretion and the rupture in the spleen, but doubt being expressed that a calculus could come from a ductless gland, careful search was made of the intestines, gall cyst, kidneys, and ureters, in the hope of finding an opening whence it could have escaped into the abdomen, but with no success. The rupture in the spleen was of such a nature as showed the spontaneous expulsion of the body, and upon a second search being made with the same result, the conclusion was forced upon us that this unpretending organ in the human economy was the *habitat* of the nodule, and that its presence, or rather its liberation, was the cause of rupture and death.

I have been unable to find on record such a thing as a *splenic* calculus, but our standard medical lexicographer (Dunglison) says in his definition of the word that a calculus may form in the substance of a body or organ, as the result of nutritive irritation, and be expelled spontaneously. Prof. Fitz says, in the new "American System of Medicine,"[1] that pathological deposits, in the form of calculi, occur in those organs which convey in canals their peculiar secretory fluids, and that these are formed of the predominating inorganic matter in them, as, for instance, a renal calculus in the pelvis of the kidney, which on analysis will be found to be composed of the urates of sodium, potassium, calcium, magnesium, or ammonium, or their phosphates or oxalates. The spleen having no duct, the question of this being a calculus is exploded and disposed of.

The next thought is of tuberculous origin, but we may differentiate that idea. There was no evidence of a tuberculous deposit in the mesentery, liver, or intestines, and where the abdominal cavity is invaded it is more apt to become general, and does not attack a small portion of one organ leaving the balance of the viscera alone. Besides the deposits are of the miliary type at first, small minute bodies, and in consistence are not hard like the one under consideration, but of a soft waxy nature, easily cut, and showing the presence of earthy deposit. They are never of such hardness as to cut out of a tissue spontaneously making a free and clean incision. There *can* be tuberculous calcific degeneration, but the agglomeration of single tubercles and consequent calcification cause a mush or cheese-like substance to form, and never hard or stony, which excludes this thought, and we now turn to the next theory, which probably is more correct.

The question of concretion presents itself as a plausible one, when we understand that cretaceous degeneration may take place in any portion of the body. Calcification is a deposit of salts, previously held in solution in the blood, under abnormal circumstances, in and upon organic matter, as the result for instance of an inflammation. This inexplicable fact is well known, and Stricker says, in the "International Encyclopædia of Surgery," that "tissues have the property of depositing lime salts. . . . As cartilage is converted into bone, it must deposite lime salts in its basis substance. But cartilage calcifies sometimes (as for example under the influence of slight inflammatory stimuli) without being converted into bone.

Of pathological calcifications of other tissues, too little is known beside the mere fact that they do occur, to warrant my considering them here." Fitz says further that concretions occur in the tissues of organs, and are collections of inorganic salts chiefly the carbonate and phosphate of calcium, hence deposited through the agency of the blood. It is not necessary that these calcifications take place in the solid portion of an organ, for viens are often found with a concretion, or *phlebolite*, and this is the development of my investigation. That this is a concretion an analysis showed it to be carbonate of lime, while the laceration in the spleen terminated in the splenic vein, enlarged and dilated, into which the vein stone I present seemed to fit quite naturally.

The absolute cause of this strange foundation is of course speculative, but so far as a general review of literature has to do with forming an opinion, the preponderance is in favor of hemorrhagic infarction, according to Cohnheim,[1] or coagulation-necrosis, as it is termed by Ziegler.

An embolus being arrested in a small artery, inducing extravasation and a secondary thrombus in the splenic vein in consequence, or a primary thrombus arising from a similar source in the vein, underwent transformation, interfering with the necessary blood supply of the surrounding area, and caused upon the surface of the spleen what Ziegler calls the "opaque yellowish white conical patch." Guillebeau endorses this opinion saying that splenic infarcts are hemorrhagic, quickly becoming decolorized and degenerated. Green[4] says that infarcts are usually found in the spleen, wedge shaped with the apex of the cone toward the centre of the organ, rapidly undergoing softening and disintegration, by regurgitation from the veins into the capillaries.

The theories of Rokitansky regarding phlebolites is that they are caused by a retarded flow in the veins, coagulation and incrustation following, and that within the concretion is an irregular brownish fissure,—the clot, which is found within the one under consideration. He writes[6] "We not unfrequently find the sheath of the spleen indurated and cartilaginous, or ossified, and at the same time ossification of the arterial ramifications and free calcareous concretions (Phlebolithes) in the veins of the organs." In *Medinische Encyclopadie* he says that in atrophy of the spleen as a result of perverted nutrition small concretions are found in the walls of veins, which are free and chalky. They show no symptoms and consequently are not amenable to treatment. Ziegler[7] says of petrifaction that the process is derived from the salts in the blood, not simply precipitated and retained, but formed as a solid compound. He mentions that large infarcts of the spleen are sometimes imperfectly reabsorbed, so that the cicatrix incloses a necrotic caseous patch

Ponfick attributes[1] the formation of these bodies to thrombi in the veins, but says it is an hypothesis Delafield and Prudden say that the contents of an abscess of the spleen as the result of embolism may dry, shrink, and become calcified Orth, in his "Lehrbuch der Pathologische Anatomie," states that phlebolites of the spleen are occasionally found, mentioning no case, and speaks of the frequency of degeneration of an infarct from embolism He says they may become absorbed and contain lime salts Birch Hirschfild claims that phlebolites are occasionally found in the spleen resulting in each case from calcification of the thrombus in enlarged veins

Morgagni[3] records a case in which a phlebolite of the spleen was discovered, in an autopsy, weighing twenty one drams Bristowe[4] has found them in the spleen and various organs of the body, and attributes their presence as the result of an adherent blood clot, undergoing degeneration Callender[5] calls them loose calculi, producing no inconvenience Bichat[6] thought they occurred in veins wherein there was slow circulation Hasse[7] found them in varicose veins, which also is Paget's theory[8] Aitken[9] calls them products of petrifaction of blood clots in enlarged veins Quain[10] says they form from a clot in a vein, and are perfectly harmless Gross[11] states that ten, twenty, or thirty phlebolites may be found in enlarged veins of the spleen and pelvic organs Merbach[12] repeats that they are found in cirsoid or varicose veins, usually in the pelvis, composed of blood and inorganic matter Cruveilhier's[13] theory is that they are developed in a clot of blood Druitt[14] in his surgery shows an illustration of a female who had several phlebolites in irregularly dilated veins under the lower jaw, which were removed with the knife

The only other case I can find on record of a knowledge of their presence *ante mortem* is reported by Gould,[15] who found in a female patient a concretion over two inches long, laying in a dilated vein transversely across the tendon of the semitendinosis muscle in the popliteal space, and its formation he attributed to a thrombus It was not removed Wyeth[16] says that phlebolites are found in cutaneous venous tumors, and in opposition to what has been cited, says that the circulation is active Our various works of surgery mention phlebolites, and the opinions are circumstantially as given above I can find also that these concretions are found in hæmorrhoids, as well as in the external genital organs

Nearly sixty cases of rupture of the spleen can be tabulated, so far as my study has gone, and about one fourth occurred spontaneously after unusual muscular exertion, for instance after vomiting, straining at stool or a sudden twist of the body In all these cases the viscus had previously suffered from disease, as malaria typhus or typhoid fevers, or some malady resulting in softening of its tissue Traumatic causes make up the other three-fourths, and are usually gunshot wounds, blows, and falls Of all cases of rupture, none is recorded as being caused by a concretion, and as death in my patient undoubtedly ensued from rupture in consequence of liberation of the phlebolite induced by hard straining at stool, this is placed on record as perhaps the first case of the kind In a communication from Surgeon-General Billings, librarian of the Army Medical Museum and Library, he says, "I have had our index references to rupture of the spleen examined There are many cases of rupture of the spleen reported, but I have not found any due to or connected with a phlebolite "

The malformation of the uterus and appendages is another rarity, and want of time forbids a lengthy discussion of the condition The text books all speak of *uterus unicornis*, but Tait[1] in his book says he has been able to find on record only one case of this singular development This he credits to Chaussier as quoted by Busch

THE TREATMENT OF DEEP-SEATED ABSCESSES ASSOCIATED WITH THE TEETH WITHOUT EXTERNAL INCISION[*]

BY JOHN S MARSHALL, M D ,

OF CHICAGO

The subject of this paper is one in which I have taken great interest for a considerable time, and have been hoping that the day would come, when some means would be suggested whereby its attendant dangers might be lessened, and the need for the use of the knife in most cases, done away with

By *deep seated* abscesses I desire that you will understand me as referring to those cases of alveolar abscess, which have extended beyond the ordinary limits, and have involved more or less extensively the structure of the jaw, with a tendency to necrosis, or have penetrated the antrum of Highmore, or have escaped from the neighborhood of the maxilla, and have burrowed downwards between the muscles of the neck, as frequently occurs in abscesses associated with the inferior teeth

Ordinarily the diagnosis of these cases is not difficult, but occasionally the cause of the disease has proved troublesome to find Abscesses discharging into the antrum or the nasal fossa, and producing offensive discharges, have been diagnosed as chronic catarrh One case occurring in the practice of Dr Edward Maynard, of Washington, D C , caused by an unerupted inferior wisdom tooth, and discharging into the larynx, setting up irritative cough with expectoration of pus and mucus, was previously diagnosed by the physicians to be acute bronchitis, others discharging at some point upon the side of the neck, have been set down as abscesses originating in the cervical glands, the result of scrofula That such

[6] Ibid Vol II, p 167 [7] Op Cit, Art 64

Ponfick attributes[1] the formation of these bodies to thrombi in the veins, but says it is an hypothesis Delafield and Prudden say that the contents of an abscess of the spleen as the result of embolism may dry, shrink, and become calcified Orth, in his "Lehrbuch der Pathologische Anatomie," states that phlebolites of the spleen are occasionally found, mentioning no case, and speaks of the frequency of degeneration of an infarct from embolism He says they may become absorbed and contain lime salts Birch Hirschfild[2] claims that phlebolites are occasionally found in the spleen, resulting in each case from calcification of the thrombus in enlarged veins

Morgagni[3] records a case in which a phlebolite of the spleen was discovered, in an autopsy, weighing twenty one drams Bristowe[4] has found them in the spleen and various organs of the body, and attributes their presence as the result of an adherent blood clot, undergoing degeneration Callender[5] calls them loose calculi, producing no inconvenience Bichat[6] thought they occurred in veins wherein there was slow circulation Hasse[7] found them in varicose veins, which also is Paget's theory[8] Aitken[9] calls them products of petrifaction of blood clots in enlarged veins Quain[10] says they form from a clot in a vein, and are perfectly harmless Gross[11] states that ten, twenty, or thirty phlebolites may be found in enlarged veins of the spleen and pelvic organs Merbach[12] repeats that they are found in cirsoid or varicose veins, usually in the pelvis, composed of blood and inorganic matter Cruveilhier's[13] theory is that they are developed in a clot of blood Druitt[14] in his surgery shows an illustration of a female who had several phlebolites in irregularly dilated veins under the lower jaw, which were removed with the knife

The only other case I can find on record of a knowledge of their presence *ante mortem* is reported by Gould,[15] who found in a female patient a concretion over two inches long, laying in a dilated vein transversely across the tendon of the semitendinosis muscle in the popliteal space, and its formation he attributed to a thrombus It was not removed Wyeth[16] says that phlebolites are found in cutaneous venous tumors, and in opposition to what has been cited, says that the circulation is active Our various works of surgery mention phlebolites, and the opinions are circumstantially as given above I can find also that these concretions are found in hæmorrhoids, as well as in the external genital organs

Nearly sixty cases of rupture of the spleen can be tabulated, so far as my study has gone, and about one fourth occurred spontaneously after unusual muscular exertion, for instance after vomiting, straining at stool, or a sudden twist of the body In all these cases the viscus had previously suffered from disease, as malaria typhus or typhoid fevers, or some malady resulting in softening of its tissue Traumatic causes make up the other three-fourths, and are usually gunshot wounds, blows, and falls Of all cases of rupture, none is recorded as being caused by a concretion, and as death in my patient undoubtedly ensued from rupture in consequence of liberation of the phlebolite induced by hard straining at stool, this is placed on record as perhaps the first case of the kind In a communication from Surgeon General Billings, librarian of the Army Medical Museum and Library, he says, "I have had our index references to rupture of the spleen examined There are many cases of rupture of the spleen reported, but I have not found any due to or connected with a phlebolite "

The malformation of the uterus and appendages is another rarity, and want of time forbids a lengthy discussion of the condition The text books all speak of *uterus unicornis*, but Tait[1] in his book says he has been able to find on record only one case of this singular development This he credits to Chaussier as quoted by Busch

THE TREATMENT OF DEEP-SEATED ABSCESSES ASSOCIATED WITH THE TEETH WITHOUT EXTERNAL INCISION

BY JOHN S MARSHALL, M D ,

OF CHICAGO

The subject of this paper is one in which I have taken great interest for a considerable time, and have been hoping that the day would come, when some means would be suggested whereby its attendant dangers might be lessened, and the need for the use of the knife in most cases, done away with

By *deep-seated* abscesses I desire that you will understand me as referring to those cases of alveolar abscess, which have extended beyond the ordinary limits, and have involved more or less extensively the structure of the jaw, with a tendency to necrosis, or have penetrated the antrum of Highmore, or have escaped from the neighborhood of the maxilla, and have burrowed downwards between the muscles of the neck, as frequently occurs in abscesses associated with the inferior teeth

Ordinarily the diagnosis of these cases is not difficult, but occasionally the cause of the disease has proved troublesome to find Abscesses discharging into the antrum or the nasal fossa, and producing offensive discharges, have been diagnosed as chronic catarrh One case occurring in the practice of Dr Edward Maynard, of Washington, D C , caused by an unerupted inferior wisdom tooth, and discharging into the larynx, setting up irritative cough with expectoration of pus and mucus, was previously diagnosed by the physicians to be acute bronchitis, others discharging at some point upon the side of the neck, have been set down as abscesses originating in the cervical glands, the result of scrofula That such

[*] Read before the Minnesota State Dental Society, Aug 1st, 1885

abscesses often prove to be serious affections, endangering the health and sometimes even the life of the individual, are well established facts I propose however, in this short paper, to confine my remarks to the more common, and from their location, the more dangerous class of these cases, viz those originating from diseases of the inferior teeth

The tendency of the suppurative products in these cases, is downwards through the external wall of the alveolar process, and to point at the lower margin of the jaw, but it also happens—especially with the molar teeth—that instead of pointing at this location, it opens through the internal wall of the alveolar process, and burrows downwards between the muscles of the neck, and may discharge into the throat, or through the external tissues at various points from the submaxillary triangle, to the superior border of the clavicle Any suggestions therefore, in regard to the treatment of these cases, which will tend to cut short the suppurative process, lessen the danger to health and life, avoid the necessity of operating with the scalpel in a location requiring such delicate dissections, and fraught with so much risk to the patient, or to prevent the unsightly and sometimes disgusting scars which follow the external opening of these abscesses, will, I think, be of interest

The treatment generally adopted in cases of alveolar abscess, is the removal of the cause by the extraction of the offending tooth, and then usually trusting to nature to complete the cure In extreme cases of this deep seated variety, an incision is made through the external tissues at the lowest point of the abscess, for the purpose of drainage In those cases, however, in which the pus has burrowed deeply into the tissues of the neck, it is quite likely that more than one pocket will be formed, consequently the treatment by incision becomes complicated, and sometimes from the dangers of an extended operation in the superior or inferior carotid triangles, would be precluded altogether The surgeon, under such circumstances, has had no alternative but to wait, trusting that the abscess would find an opening for itself at less risk, before the patient should die of pyæmia The treatment which is suggested comes to our relief in this emergency and from past experience with it I am prepared to say, at least, that the duration of these cases can be materially shortened, and many of them speedily cured, without resort to any other operative procedure than the extraction of the diseased tooth, and the injection into the sac of peroxide of hydrogen With the introduction to the profession of the peroxide of hydrogen, a valuable antiseptic and germicide has been placed in our hands Ophthalmologists and aurists have found it very useful in the treatment of diseases of the eye and ear, with purulent and muco purulent discharges, and dentists have been signally successful with it, in removing the putrid contents of the pulp chamber in devitalized teeth, in treating the ordinary alveolar abscesses, and phyorrhea alveolaris

By injecting an abscess of this deep-seated variety with H_2O_2 introduced through the alveolus of the extracted tooth, the purulent contents can be thoroughly evacuated The oxygen is set free on coming in contact with the products of decomposition, which distends the cavity and forces out the pus through the alveolus, by mechanical pressure Two or three injections of ʒss to ℥j according to the extent of the abscess, may be required to completely remove the purulent matter, and if given opportunity, it will search out and purify every hidden receptacle I have had several opportunities, since the introduction of H_2O_2 to the notice of dental surgeons by Dr Walter Coffin, of England, at the London International Medical Congress in 1881 (Transactions of the Seventh International Medical Congress)—and to whom this credit is due—to test its efficiency in this class of cases, and in extensive periosteal inflammations of the jaws

In one case, a Mercy Hospital patient, Mary N, Irish, aged 24 years, suffering with a deep seated abscess associated with the right inferior wisdom tooth, and which had been progressing for several weeks, and confining the patient to her bed for 26 days, with pulse ranging from 100 to 116 and temperature from 101° to 104 8°, was speedily relieved by extracting the tooth, and evacuating the pus—the abscess extending down the neck 4½ inches below the margin of the gum, as was ascertained by the probe—the pulse dropped from P 104 T 104 8° on the previous day, to P 96, T 103° two hours after the operation H_2O_2 was ordered to be injected into the abscess ʒss every four hours, this was followed by a decrease in the temperature of one degree each day for three days The patient then refused to submit to the further use of the remedy, as the evolution of the gas, by distending the sac caused pain This was immediately followed by an increase in the pulse rate, and an elevation in the temperature On the fourth day afterwards they had reached P 101, T 104°

H_2O_2 was again used as before, and the pulse and temperature again rapidly fell, but through the obstinacy of the patient, the treatment could not be carried out with any degree of satisfaction still the fact was established that the peroxide of hydrogen, antisepticized the pus and evacuated the sac, as indicated in the rapid improvement of the symptoms

Another case was that of a little girl aged 11 years, with an abscess originating from the right inferior first molar, and extending into the tissues of the neck, accompanied with extensive swelling and tenderness but with no acute pain The swelling of the parts had followed an attack of severe pain in the tooth and jaw, from which she had suffered three weeks previously For a week, the jaws had been closed, and the only food taken each day, was a small quantity of milk The child had been confined to the bed for a part of the time, and when presented for treatment, looked decidedly ill

The tooth was extracted under ether, and the pus cavity found to extend downwards three inches below the margin of the gum Very little purulent matter followed the extraction of the tooth, but on injecting the pocket with H_2O_2 large quantities were evacuated The injections of H_2O_2 were continued once per diem for six days, when the patient was discharged cured Under the ordinary treatment, I should have expected this case to have continued for a much longer period, and perhaps to have seen it finally point at some location lower down the neck Other cases, very much like this one in character, might be mentioned in proof of the value of this remedy

One more however, might be related with profit

This was a case of a lad 9 years of age, who had received a traumatic injury of the inferior jaw, by a fall from his bycycle, and which resulted in an extensive acute periostitis, involving the teeth and jaw, from the location of the second temporary molar of the left side, to the ramus of the jaw on the right side, all of the teeth between these points were loose, pus exuded from the gums at the necks of the teeth, and I feared extensive necrosis

The treatment adopted was injections of $H_{2}O$ beneath the gums at all points where pus was found to exude The condition of the anterior part of the mouth began to improve at once, but opposite the first permanent molar, at the lower margin of the jaw, it was necessary a few days later to open an abscess which was about to point at that location The injections were kept up for two weeks All discharge had then ceased, the teeth had become firm, and the patient was discharged

Dr Harlan has recently called attention to the use of $H\ O$ in purulent conditions affecting the maxillary sinus (*Archives of Dentistry*, p 204, May, 1885), and I would suggest that it will be found equally valuable in the hands of the surgeon in nearly every variety of suppurative inflammation, especially in periostitis, necrosis and deep seated abscesses, when there is difficulty in completely evacuating the purulent matter by the ordinary means

CITRIC ACID IN THE EXTIRPATION OF MALIGNANT TUMORS

BY C M FENN, M D,

OF SAN DIEGO CAL

Prior to the revelations of the microscope, morbid growths, with few exceptions were looked upon as local manifestations of some blood dyscrasia They were known to be environed by a zone of infiltration or degeneration, of varying area, and the question of recurrence after an operation was supposed to depend largely upon the extent of the incisions The desire, however, to preserve symmetry, especially if about the face, and to hasten cicatrisation, frequently induced the surgeon to circumscribe his operative procedures, relying subsequently upon antiseptic applications to sterilize flaps and adjacent tissues Unfortunately, it was seldom possible thus to reach the extreme boundaries of the disease, hidden as they were to sight, and the materies morbi, with lymphatics and blood-vessels as avenues (?), quickly invaded other tissues and viscera, or the increased supply of nutrient material, in the absence of the central mass, soon precipitated a recurrence at the original site This process was all the more rapid after attempted extirpation by pastes and caustic lotions Consequently the impression prevailed that surgical interference merely postponed the fatal denouement

Cellular pathology, however, has modified some of these theories, while confirming others It has taught us, I think, that tumors, excepting, perhaps, the essentially cancerous ones, are for the most part of local origin, whether homologous or heterologous as to the tissue from which they arise, that the drier ones are seldom recurrent, and that when metastotosis and recurrence take place, it is through the medium of morbid juices, which invade connective and other loose tissues, and set up foci of disease in other portions of the economy These later investigations, in my opinion, should encourage the surgeon to attempt at least the radical extirpation of all kinds of tumors, though custom and classification may have placed some of them among the "*noli me tangere*" class

While yet a student, some twenty years ago, it was my privilege to assist in the removal of a great many epitheliomatous and other abnormal growths, and the rapidity with which some of them recurred impressed me most forcibly at the time In many instances plastic operations were successfully undertaken to conceal deformity and promote cicatrisation, but at a later period these only added fuel to the flames In later years, having adopted the non-systemic theory, and recalling the well-known antagonism of citric acid to diseased tissue, while comparatively innocuous to healthy cells, I devised a method for the extirpation of doubtful and malignant tumors which I shall be glad to see thoroughly tested It consists, as will be noted, in an attempt to segregate the degenerated zone before using the scalpel

The notes of a few cases, of dates sufficiently remote to justify conclusion, will best illustrate the process

Col H T C, aged 48, of undoubtedly cancerous antecedents, his grandfather and father having succumbed to malignant disease of the face, had been appealing to thirty-third triturations for the removal of a suspicious tumor situated upon the left ala of the nose Notwithstanding the *attenuations*, the disease had rapidly extended down the side of the nose until a large segment of it rested upon the cheek Its track, fully an inch in length, and more than six lines in width, resembled the cicatrix of lupus exedens When first examined by the writer the tumor, now larger than a filbert, had a sessile attachment, an encrusted summit, and, in addition to an indurated margin, was evidently exceedingly vascular The elderly gentleman, remembering the fate of his ancestors, whose lives had scarcely been prolonged by the frequent operations to which they had been subjected, was naturally very despondent, and while decidedly opposed to the employment of caustics, he was correspondingly incredulous as to any permanent relief to be obtained from the knife

At the outset my armamentarium included an old hypodermic syringe and a saturated solution of citric acid. The needle was introduced deeply into the base of the growth, and about half a drachm of the solution injected. The entire mass became blanched at first, following which a few drops of the acid, mingled with blood, escaped at the surface. Beyond an insignificant tingling, the suffering was so slight that he voluntarily returned on the following day for a repetition of the operation. At intervals of two and five days the process was repeated, until a large zone had been thoroughly saturated with the solution. The size of the tumor gradually diminished until a nodule as large as a small pea alone remained. After the lapse of about three weeks this nucleus was raised upon a tenaculum and excised. The hæmorrhage, as had been anticipated, was quite profuse, but yielded readily to styptics and compression. During the entire period of manipulation, the local irritation seldom required restraining lotions. More than six years have already passed without any evidence of recurrence, and the colonel feels that he has made a fortunate escape.

A second case occurred in the person of a middle-aged matron, who also gave a history of a cancerous diathesis in her family. The tumor was situated between the eyes, and was slowly encroaching upon each of them. Immediate excision could not have been undertaken without leaving a most unsightly deformity. Subcutaneous injections of a similar kind were therefore used, the needle point being directed at times toward the centre of the mass, and, again, outwardly, in various directions. A diminution of the induration was soon perceptible to the touch at the periphery of the zone, and continued until an elliptical incision, having a horizontal diameter of not more than twelve lines, included the entire growth. Three years have now elapsed without a return of the disease.

Still another illustration of the vagaries of the cancer and the possibilities of this treatment may not be out of place here. A lady, of perhaps 40 years, stated that about two years previous to our interview, and without any assignable cause, a hard lump made its appearance, a little to the right of and below the right breast. It had been twice operated upon in a distant city, without removing the indurated mammary and axillary glands! After a brief interval of repose it had again come to the surface, and was now manifesting increased virulence. A fungoid mass, as large as the top of a tea-cup, occupied the original site, and was so painful that large doses or opiates only procured temporary relief. It was evident that the system was so saturated with the cancerous juices as to preclude further surgical interference. An operation promising even a temporary respite would have involved excision of the breast and axillary glands and an area of integument at least five inches in diameter. As in the other cases, citric acid was injected into the tumor and adjacent tissues, with the results that pain was mitigated, hæmorrhage somewhat restrained, besides other evidences of improvement. It was, of course, impossible to stay the progress of the malady by any course of treatment.

San Diego, Cal., July, 1885.

MEDICAL PROGRESS

MATERIA MEDICA AND THERAPEUTICS

PRESERVATION OF ALKALOIDAL SOLUTIONS.—Much has been said and written on this subject of late, and many have been the suggestions. In the British Pharmacopœia most of the alkaloid solutions are ordered to be preserved with rectified spirit in certain proportions, the solution of sulphate of atropia being an exception. There cannot be much objection to the use of this preservative when the medicines are intended for internal use *per os,* but when required for dropping into the eye, ear, or other delicately lined part of the body, or for subcutaneous injection, the use of spirit then becomes objectionable because of the smarting pain produced. Liquor atropiæ, B. P., is a notable example, as also the hypodermic injection of morphia. In place of spirit we have many useful substitutes, or means of avoiding this particular difficulty: 1. The use of neutral solutions of the alkaloids with tartaric, salicylic, and other organic acids, 2. The addition of phenol, thymol, salicylic acid, boracic acid, and such antiseptic substances in minute quantities, 3. The use of camphor-water, glycerine, etc., as the solvent. With regard to the first method, tartrate of morphia may be found a very useful salt for subcutaneous use, as it is readily soluble in water, keeps fairly well, and causes less irritation than the acetic solution. The same applies equally to atropia solution, but it may be mentioned that each of these does not keep for very long periods without the usual fungous formation. The second method may be objected to because of the powerful nature of the substances named, but there need be no fear, because a very small quantity suffices. The salicylates of the alkaloids are known to keep fairly well in solution, even when exposed to the air, and their effect in such a combination is not impaired. Apomorphia solution may contain a trace of phenol to preserve it. Cocaine solutions are said to be useless after two weeks if not preserved by means of some such preparation as a saturated solution of salicylic acid, and very likely this may account for the failure experienced by some practitioners in obtaining the 'local anæsthesia" said to be produced so markedly by this recently much used article of materia medica. The third method may be employed with considerable advantage for solutions of atropia, and doubtless also for eseria, pilocarpia, duboisia and gelsemia, when they or their salts are easily soluble in this solvent. Glycerine dissolves some alkaloidal salts very readily, and when diluted with a little water, to thin the product a little, may serve well for hypodermic injection, the pain produced sometimes by the glycerine, especially when used hypodermically, being greatly mollified by the addition of the water. Another method recently recommended by Dr. Macnaughton Jones for the preservation of these solutions is based upon the supposition that light aids in bringing about these changes. He proposes the use of a glass bottle colored blue or yellow, and provided with a vulcanite air-tight stopper, flanged with india rubber, and having a little vulcanite pipette, surmounted by a small cap By inversion and warmth of the hand a drop or more may easily be obtained without waste of material (which may be expensive), and with the additional advantage that the alkaloidal solution keeps longer, as the air does not so readily exert its influence in introducing fungus spores —*Birmingham Medical Review*, May, 1885

MEDICINE

New Experimental and Clinical Researches upon Bright's Disease —Prof Mariano Semmola deduces the following conclusions from the results of his latest experimental and clinical researches upon Bright's disease

1 Albumen can traverse the renal tissue without any previous alteration in the histological elements of the kidney, and without leaving any trace of its passage

2 If the passage of albumen be persistent, the first effect is hyperæmia with intraglomerular and intratubular hæmorrhage, and the capsule is distended in a mass after boiling, and sometimes is simply raised and separated from the glomerulus by an empty space There is also observed considerable migration of leucocytes without any alteration of the epithelium The urine contains hyaline cylinders These are the first results of an inflammatory action in relation with the functional activity of the kidney

3 If the functional process persist beyond even eight or ten days, especially with the injection of albumen in the proportion of one gramme for every thousand grammes of the animal's weight, the invading process is attended by a mild inflammatory action, in addition to a turbid swelling of the epithelium of the tubules, fatty degeneration, and thickening of the intratubular connective tissue

This proves that the functional activity, which the kidney must sustain in the gradual and prolonged elimination of unassimilable albumen, is apt to provoke successively in different parts of the organ an inflammatory process, which, commencing in simple hyperæmia, may result finally in the establishment of interstitial nephritis Prof Semmola is convinced by repeating the experiments and injecting very minute quantities of albumen, in order to have the experiments well under control and preserve the life of the dog for seven or eight months, that they will result in producing the last phases of the large white kidney—that is to say, the atrophic kidney

4 The histological alterations in the kidney persist for some time after the injection of the albumen without producing a continuation of albuminuria

5 Along with the elimination of albumen with the urine is also observed *albuminocholia*, that is to say, the elimination of a certain quantity of albumen with the bile

In relation with the above experiments, Prof Semmola proposes to continue his researches on the pathology of Bright's disease with the following experiments to determine

1 The comparative influence upon renal elimination produced by the injection of albuminose, which is presumably more assimilable, such as serum of blood, albumino peptones, white of egg, and milk

2 The influence of albuminous injections upon the crasis of the blood, and upon the elimination of a quantity of albumen greater than that injected

3 The influence of albumen injections upon degree of activity in the combustion of nitrogenous matters and upon the production of urea

4 The influence of albuminose injections upon the dyscrasic condition of the blood, and their relations with the production of anasarca —*La Medicina Contemporanea*, June, 1885, *Med News*, Aug 1, 1885

The Transmission of Phthisis Between Man and Wife —Professor Potain has recently delivered a lecture on this subject, which is published in the *Revue de Medecine*, June 10, 1885, in which he gives some very interesting data His first case is that of a woman 40 years of age, who died of rapid tuberculosis She had no tuberculous antecedents, and enjoyed good health previous to her contracting the disease She was a housemaid, and married a man who died of lung trouble after being incapable of any work for three years During all of his sickness she had the sole care of him and the children, and three months after his death entered the hospital in a typhoid condition, dying in six days Auscultation of the chest gave evidences of congestive pneumonia, with generalized bronchitis, but the general symptoms were such as to indicate tuberculosis, which the autopsy confirmed

Potain reviews the subject of the old popular belief in the contagion of phthisis, as agreed to by Aristotle, Hippocrates, and Galen, and the laws in Italy, in the middle ages, which prescribed isolation for phthisical cases, then the progress of pathological anatomy gradually negatived this view until the researches of Laennec, Andral, and finally Virchow, did away entirely with the belief In 1865 Villemin, an army surgeon, from the frequency of tuberculosis among robust young men for the most part yet living in common, and from his experiments on the subject, was the first to declare that tuberculosis was an infectious, zymotic disease, from this date we come to Klebs, in 1877, noting bacteria in the sputa of phthisical subjects, and finally Koch's well-known demonstrations in 1882

Musgrave Clay, in his thesis (1879), gives 111 cases of contagion Prof Potain considers particularly the transmission between man and wife, and refers to Bernard, 1881, who gives the case of a young girl 18 years of age, of a family free from tuberculosis, who married a man in delicate health and had no children The man died phthisical in five years time Three months later his widow had her first attack of hæmoptysis, a cough followed, and she died the following year. Guérin (of Nantes) reported the case of a young man who became tuberculous at about the age of 21, at 27 he married a large, strong woman, without tuberculous antecedents, they had no children Five years later the wife died of phthisis Buder (of Haut-Rhin) gives a similar instance A merchant, born of a consumptive mother, who lost one brother from phthisis, married a young girl of 17, free from any tubercular heredity He died in 1871, and his wife in 1875 Three other cases are cited from as many authors where the wife communicates the affection to the husband, and one case where a phthisical husband, after losing a child from tuberculous meningitis, and transmitting his disease to his wife, dies of consumption His widow marries again, dies of tuberculosis, and her second husband, in his turn dies of tuberculosis, a sister of the wife, who took care of her, dies of the disease and her husband also dies of it The contagion is supposed to have been transmitted successively to all of these cases of previously healthy persons, free from tuberculous antecedents, by the first husband

That the transmission may occur in the absence of the pathological condition, a case taken from the Bulletin of the Clinical Society of London (Hermann Weber, 1874,) shows very strikingly A sailor of tuberculous stock, and who, during adolescence, suffered from hæmoptysis, believed himself cured and married at the age of 27 His wife died after her third confinement A year later he re-married, his second wife died within a year a third died eight months after her second confinement, a fourth died nine months after her first confinement During the whole of this time the man appeared to be in good health, only coughing a little and expectorating a few mucous pellets on rising in the morning A few years later he died tuberculous

In most of the cases cited the women who contracted phthisis by contagion had borne children, in fact pregnancy is a debilitating cause which predisposes to tubercular infection But the transmission can take place without the intervention of pregnancy Musgrave Clay gives seven cases of this character

Cases are also given in this paper to show the transmission of phthisis among others than those who are married, and where there has been no nocturnal cohabitation It would seem, also, as if, in certain cases, that the tuberculous infection took possession of the house itself, thus perpetuating itself M de Lamare (1859) cites three cases of deaths of occupants, who lived necessarily in the same furnished apartment where a death occurred from phthisis, neither the furniture nor hangings being disturbed These three occupants were in no way predisposed to tuberculosis by their antecedents, their constitutions, or their modes of life The house having been refurnished no more cases occurred

The phthisis of monasteries, of convents, in the army, and in crowded cities, receives in turn due consideration But Potain lays special stress upon the danger of contagion in hospitals Among the cases which he cites is one from Bergeret, of a soldier whose antecedents were exceptionally good, and who, entering the hospital for some slight affection, was placed between the beds of two cases of consumption He became phthisical, and, returning to his family, contaminated successively his mother, two brothers, his father, a neighbor and her husband

As to the mode of transmission, he thinks there is no proof to incriminate the sweat, or the expired air, but that it is due to the inhaling of the dust of the dried sputa

SURGERY

A WORSTED TRUSS FOR INFANTS —MR LUND, in his second lecture, recently delivered at the Royal College of Surgeons, referred to a form of truss which is free from many of the disadvantages inseparable from the usual form of instrument when applied to a very young patient He said the truss, or the mechanical appliance which he should specially recommend for the relief of inguinal hernia in the infant, is certainly the worsted truss, a mode of treatment little known, he believed, but yet very simple and effective It is described in *Ranking's Abstract* (vol ix, p 131) He had used it in several cases where he had been consulted on the subject of the early appearance of inguinal hernia in young infants A skein of worsted, known as "Berlin wool," tied together, is applied around the pelvis and across the front of the abdomen One end or loop of the worsted is placed directly over the outer abdominal ring through which the protrusion of the hernia is likely to take place, or, if the hernia has already become scrotal, it must be first reduced, and pressure made over the spot, if the child should cry or struggle much The folded worsted is passed horizontally across the abdomen, just above the line of the crest of the pubes, to the opposite side, round the hip, behind the pelvis, and over the hip of the side of the hernia The folded end is then passed through the loop of the skein, and will here form a knot or bulged portion, which must be carefully adjusted, so as to lie against the hernial opening, and, being carried down the upper part of the thigh, between it and the scrotum, if it be a male child, it is brought round the external side of the thigh, near to the top of the great trochanter, and there tied or fixed with a safety pin to the band of worsted already round the pelvis With a little care, this arrangement of the worsted may be used as an excellent defence against the distension of the weak inguinal canal, and the descent of a hernia into the scrotum It is not powerful enough, nor could it easily be kept in position, when the child is old enough to run about, but on the principle that prevention is better than cure, it is a means of relief to which we can have recourse at a very early date, certainly before we could expose the infant to the torture of an ordinary hernia truss, however weak the spring might be It has this advantage, that the infant can be washed with the truss still in its place, a fresh one can be then applied, and the old one cleansed and used again —*British Medical Journal*, June 13, 1885

THE RADICAL CURE OF CANCER OF THE RECTUM —MAURICE POLLOSSON, in an article on this subject in *La Lyon Médicale*, proposes to operate for the radical cure of cancer of the rectum by first performing colotomy, and then making a secondary operation for extirpating the cancer The preliminary operation renders the extirpation of the neoplasm more easy and less subject to subsequent complications Polosson has tested this method in one case, making the artificial anus in the iliac region This case recovered —*Revue des Sciences Méd*, July, 1885

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET
CHICAGO, ILLINOIS.

SATURDAY, AUGUST 22, 1885.

MORE SIGNS OF PROGRESS

The leading editorial in the *Medical News* for the 15th inst. contains the following: "The action of the Original Committee—of the American Medical Association—and of the New Committee is now generally understood, and there does not seem to be much use in further comment and criticism upon what is past. The important question now is as to the future. Is there any way by which the impending disgrace can be averted? If there is, it must be such as will induce those who have withdrawn from the organization to return and co-operate heartily."

If it is true that the *News* and its limited number of eminent friends in Philadelphia, who so hastily undertook to obstruct the work of organizing the International Congress are beginning to realize their position in direct alliance with a faction in New York, whose well known organs, the *Medical Record* and *New York Medical Journal*, have been losing no opportunity to heap obloquy upon the American Association for years, as an unnatural and uncomfortable one, it is not difficult for them to find a way out of it if they do not delay too long. If they want the Code question dropped entirely, they have only to cease agitating it, and sever their official alliance with those who openly repudiate it. None know better than the *News* and its eminent friends that, so soon as the general officers of the Preliminary Organization of the Congress and the officers of the several Sections are appointed, and the appointees accept, those general officers and the Chairmen of the Sections constitute the Executive Committee of the Congress, and the whole management of its scientific interests passes into their hands, leaving but little further for the Committee of Arrangements to do. And inasmuch as the Committee of Arrangements, at its regular meeting in Chicago, actually re-nominated the same President of the Congress, twelve out of sixteen of the same Chairmen of Sections, while the four new Chairmen of Sections and the new appointee for Secretary-General were every one of them men of the highest standing, and well known both in Europe and America, it is apparent to every candid mind that no reasonable objection could be made to the proposed leadership and *personnel* of the Organization.

In regard to the Rules for regulating the conditions of membership and the working of the Congress, it is well known that all the Rules relating to the latter were adopted by the New Committee without change. The only change of importance proposed was in Rule 1, which related to the terms of membership. The change in this rule proposed by the Committee was not satisfactory, and it is still open for further consideration and adjustment at the coming meeting of the Committee on the 3d of September. In our issue of August 8th, we gave two propositions that had been suggested for regulating the American Membership of the Congress, both of which were amply liberal—the one retaining the representative principle, and applying it to all the national special organizations, as well as to the National Association and the State and local societies in affiliation therewith, the other opening the door of the Congress, so far as its scientific proceedings and interests are concerned, to all members of the regular profession who might choose to register and take their tickets of admission. If either of these propositions is satisfactory, let the *News* say so. Or, if it will be more satisfactory to all parties, and will be accepted as a basis of adjustment to have the Rule 1 read simply as follows: "The Congress shall be composed of members of the regular medical profession who shall have inscribed their names on the register, and taken out their tickets of admission," thus making the terms of membership alike to all, American and foreign, let the *News* and its friends indicate this, and the proposition will receive a fair consideration. They cannot longer maintain their dog-in-the manger policy on purely personal considerations without passing into history as persistent obstructionists, who place their personal prejudices above the honor and welfare of the profession to which they belong.

The 3d of September is near at hand. If those members of the profession who so abruptly abandoned the honorable and responsible positions to which they had been assigned wish to retain those positions, and aid in maintaining the honor and interests of the profession of their country, let them move in that direction soon, or their places will be filled by others equally eminent, and the good work will move on without them. To talk of restoring the Original Committee of eight appointed by the Association at Washington, and enlarged by its own action, is simply childish. It is perfectly well known that the Original Committee appointed at Washington is now an integral part of the present Committee of Arrangements, and has no existence in any other capacity or connection. The enlargement of the Original Committee by the addition of a representa-from each State, and from the Medical Corps of the Army and Navy, instead of a less number selected from a few cities, neither lessens the efficiency nor detracts from the dignity of the Committee, as simply a Committee of Arrangements. And such Committee will proceed with its work in a true conservative liberal spirit, and will complete the preliminary organization of the Ninth International Congress on as liberal a basis, and under the official leadership of as eminent and learned men as the profession in America contains.

Our European brethren need have no fears of being met by codes or partisan questions on their arrival here. At the Copenhagen Congress they accepted an invitation to hold the next Congress at Washington in 1887, extended through a Committee appointed and commissioned by the American Medical Association, and in behalf of the profession of the United States. If they do not prematurely interfere, when the time comes they will meet with as liberal and cordial a reception, both from the representatives of the medical profession of these United States and from the highest officials of our National Government, as they have met in any of the Congresses heretofore held in Europe.

POST PHENOMENA OF DECAPITATION

Some time ago, Paul Bert suggested a series of experiments on recently decapitated persons, with the idea that by careful and immediate experimentation considerable light might be thrown on certain physiological problems. Physiologists in Paris have found it impossible to make these experiments on account of certain formalities which are thought to be necessary in that city when a criminal has been decapitated. MM. P. REGNARD and P. LOYE, however, have been recently, July 2, 1885, enabled to carry out the ideas of Bert to some extent in Troyes, the most careful preliminary arrangements having been previously made. Their report is to be found in *Le Progres Medicale*, of July 18.

When the condemned man was placed on the instrument he seemed to be in a state of syncope, the mouth and eyes were widely open, and he seemed quite insensible. At the very moment that the knife severed the head from the body a general contraction of the muscles of the face was easily seen, but the horrible facial distortion which then followed was probably due more to direct excitation than to a psychical phenomenon. Within less than a minute after the decapitation the cadaver was placed in a carriage. At this time the complete inertia of the body was quite inert, the face was composed, the features in repose, and the eyes and mouth closed. There were none of those irregular movements which many authors attribute to the bodies of decapitated persons, or which they report as occurring when certain of the lower animals are decapitated. Next the experimenters attempted to lift the body, when it was found to be in a state of complete contracture, both of the extensors and flexors, the whole body could be lifted by lifting the extremity of one limb, and it was impossible to flex the knees or thighs. The same was found to be true, to a certain extent, of the head. The eyelids, which were widely open when the knife fell, were now firmly closed, so much so that it was difficult to open them sufficiently to carry out a part of the experimentation. This state of general contracture lasted for two or three minutes (it being almost impossible to take the time with precision on account of the rolling of the carriage, which was moving very rapidly).

It has been asserted and denied that the reflexes persist after decapitation. In this case, after the cessation of the rigidity, the skin of the body was pinched and the soles of the feet were tickled without the least movement being provoked; the patellar reflex had completely disappeared. The surface of the eye was violently irritated without causing the least contraction of the lids or of the muscles of the face. Violent irritation of the cord at the point of section gave no results. The pupil, which was moderately dilated, contracted but very little on the approach of light. Thus, three minutes after decapitation, it was impossible to observe any spontaneous movement, or even a reflex, except that (very slight) of the pupil.

Having arrived at the hospital, where a room had been carefully prepared, a series of experiments was commenced on the actions of the pneumogastric nerve, the first being with reference to its action on pulmonary contractility. The experiments of Williams and Paul Bert, on dogs, show that the muscular fibres of Riessessen, disposed in a circular manner about the bronchi, are innervated by the vagi. But in the dog, it should be remembered, the pneumogastric is intimately connected with the sympathetic, so that it is very difficult to say with certainty to which of these two nerves is to be attributed the influence on the pulmonary muscles. In man, however, this connection does not exist, so that it was comparatively easy to solve this question. The pleuræ were opened so as to allow the air to enter freely, a differential water manometer was then introduced into the trachea, and firmly secured, and an induced current was then passed through the vagi. The liquid immediately commenced to ascend in the manometer, slowly at first, and followed by an equally slow descent after the current was broken. This was done thirty two minutes after decapitation; it showed that pulmonary contractility is due to the action of the pneumogastric nerves.

At sixty minutes, after opening the thorax, one pole of the battery was placed on the surface of the lung and the other on the trachea in the mediastinum, when the pulmonary tissue was directly irritated the fibres of Reissessen contracted, and the liquid slowly ascended in the manometer.

Forty-five minutes after decapitation the abdomen was opened: no spontaneous movements of the stomach or intestines were observed, nor were any caused by the contact of the air. On irritating the vagi there were immediate marked movements of the stomach and intestines, extending as far as the transverse colon. According to Longuet this motor action for the stomach is only produced when the stomach is full of food; but in this case the stomach was completely empty. The stomach was then opened, and the current applied to the vagi; almost immediately small drops of gastric juice began to appear over almost the whole surface of the gastric mucous membrane.

The final experiment was on the dorsal and palmar interossei, and lumbricales; it was found that their action is that which has already been assigned by Duchenne, of Boulogne.

It will be seen that these experiments were not only of great interest but of considerable physiological value. So long as decapitation is the mode of capital punishment in France, it seems that further experiments in this direction might be carried out.

THE TOXICITY OF NORMAL URINE.

The toxicity of normal urine has been a disputed question for a long period of time. The weight of evidence is on the affirmative side, although the immediate poisonous principles are not known. Urea, uric acid, kreatin, and the potassium salts have in turn been incriminated. Recent investigations, however, point to the existence of poisonous alkaloids in normal urine. M. CHAUTEMESSE has summarised the history of the subject, which is well abstracted in two leading articles, appearing in the *British Medical Journal*, June 6th and July 4th, 1885.

Alkaloids have been found in putrid albumens, bile and normal muscle-juice by Gautier and Pouchet. Brouardel and Boutmy, published in 1881, a distinguishing reaction between the vegetable alkaloids and the ptomaines. The alkaloids of putrefaction, in the presence of potassium ferricyanide and ferric chloride yield the Prussian blue coloration. In 1880, Pouchet found an alkaloidal substance in normal urine, which, in combination with hydrochloric acid, formed double salts with platinum, gold and mercury. Brouardel's discovery that "alkaloids exist in the bodies of living beings, which have been generated in the alimentary canal, and probably elaborated by the vegetable organisms there present acting as the agents in intestinal putrefactions," marks an important advance beyond the results of the labors of Selmi, Gautier, Pouchet and Boutmy. Part of these intestinal alkaloids are absorbed into the blood, further elaborated by the kidneys, and appear in the urine.

PROFESSOR BOUCHARD, at a recent meeting of the Société de Biologie, read an interesting and valuable paper on the toxic qualities of normal urine. In the light of the recent progress of physiological chemistry, briefly detailed in this paper, the results of Professor Bouchard's experiments are clearly intelligible. The fact of toxicity of the urine was established by the injection of specimens of urine into the veins of frogs and rabbits.

Following the injection of normal urine into the veins of a rabbit, Bouchard observed "contraction of pupils, slow respiration, muscular weakness, lowered temperature, abolition of reflexes, torpor," and death as the result of arrest of respiration. It is a well-known fact that 90 cubic centimètres of water for every kilogramme of its body-weight may be injected into the veins of an animal without the production of mechanical effects. In Bouchard's experiments, the quantity of fluid used was not the tenth of this amount, so that the effects were of a true toxic character.

Bouchard next attempted to determine the particular constituent, to which the poisonous character was due. Without entering into the details of the experiment, it was found that urea, uric acid, kreatin, and the potassium salts, alone and combined, "though undoubtedly poisonous, were not so in the small quantities contained in the urine injected. He concludes that there are numerous poisonous principles present, which do not reside in one, but in several of the urinary constituents." The poisonous principles are not volatile.

Very recently, Lépine and Guérin have demonstrated that these alkaloidal bodies are increased in various acute diseases. Thus in typhoid fever and pneumonia, the toxicity of the urine was greatly increased, while in the urine of diabetes, catarrhal jaundice, and cirrhosis with jaundice no increase of toxicity was observed.

JOURNALISTIC CHANGES.—We have received the two first numbers of Daniel's *Texas Medical Journal*, a new monthly of 50 or 60 pages, earnestly devoted to the educational, scientific and practical interests of the medical profession in the Lone Star State. It is published in good style, on good paper and fair type, at Austin, Texas. It is both edited and published by F. E. Daniel, M. D., a man of great activity, independence of thought, and a peculiarity of expression that will always attract attention. These copies also indicate the active support of a fair number of contributors, and we trust the enterprise of our friend Daniel will be characterized by long life and abundant prosperity.

BACK NUMBERS WANTED.—Copies of Numbers 2, 6 and 16, of Vol. 1, Numbers 22, 24 and 25, of Vol. 2, Numbers 2 and 4, of Vol. 3, and Number 2, of Vol. 4, are wanted to complete files of this journal for binding. We will pay 50 cents a copy for as many of the Numbers just mentioned as may be sent to this office in a good condition, during the next 30 days.

SPECIAL ARTICLE

THE BATTLE OF CELLS AND BACTERIA

BY RUDOLPH VIRCHOW

[Translated for the JOURNAL from *Virchow's Archiv*, Bd. CI, Hft. 1, by A. S. von Mansfelde, M. D., of Ashland, Neb., assisted by Alice E. Huff, M. D., of Ashland, Neb.]

Many years ago, as is well known, I formulated the proposition "Omnis cellula a cellula," as a substitute for that of Harvey, "Omne vivum ex ovo." The cellular theory of life immediately pointed to a cellular theory of disease, and my conclusions were the result of comparing the lowest plants and animals with the cells of higher plants and animals. Just at the time when I arrived at the theory of evolution, from the epigenetic conception of various pathological processes, when I put the parental propagation of cells in place of plastic substances and deposits, so called unicellular plants and animals occupied the foreground of attention in botany and zoology. Much in the conception of these structures has since been changed; yet the progress of knowledge has given new and stronger proofs that the vital qualities and energies of individual cells must be compared with the vital qualities of the lowest plants and animals. The natural consequence of such a conception is the necessity of a certain *individualization of the cells*. If even the lowest plant, the lowest animal has a kind of personality, then this same quality must necessarily belong to the individual living cell of a composite organism. I will not deny that this form of contemplation may give rise to mistake, and that there is danger of deducing therefrom a new form of vitalistic mysticism. But from mistake and exaggeration no human thought is safe. A cell which nourishes itself, which, as is now said, digests, which moves, which excretes, is certainly an individual, a working, active being, and its activities are not simply products of external influences, but the products of internal processes, closely related to the continuation of life.

As much is accomplished by the least active animal cell, many accomplish much more, and therefore we must accept these elemental organisms as individualities. Such a conception is not mysticism, but pure realism. Singularly enough persons have existed who, from time to time, according as new phases in the activities of cells became known, or occupied a prominent place, with these new facts assumed the extinction of the cellular theory. Even such extraordinarily instructive and demonstrative facts as the automatic movement and the migration of cells have been conceived as invasions into the domain of the cellular theory, when instead of this, they most brilliantly confirm it. It is entirely different with the external influences which the cells experience. It is not to be denied that etiology as compared with phenomenology has a long time been somewhat neglected. This became the more apparent when the parasitic micro organisms in constantly increasing numbers, entered into pathological consideration. Perhaps the majority of contemporaries were dazzled by it. It seemed as though they held the whole of the old wisdom as worthless. One can understand this conception even if he does not subscribe to it. But it may be well to give an explanation of how it came about that the importance even of those micro organisms which were known was not always immediately realized. What the conception of these things was a generation ago I have shown in my article on parasitic plants in my text book of "Special Pathology and Therapy" (Erlangen, 1854, vol. 1, p. 355). Since Bassi, in 1835, recognized the muscardine disease of silk worms, Schœnlein in 1839, the fungus of favus, and Julius Vogel, in 1841, the "soor" fungus, the conception that parasitic plants could give rise to specific diseases in the body has become a familiar one. Different pathologists have immediately, from the rather scanty facts, devised a far-reaching theory of parasitic diseases. I can affirm that a prejudice against such a presumption did not exist, and in this connection I may say that I at that time published a series of, in my opinion, very careful observations on Pneumo and Onycho-mycosis (*Virchow's Archiv*, 1856, Bd. ix, page 557, plate iv). At the commencement of this article I gave expression to the reasons why, in the 15 years since Schœnlein and Vogel, almost no progress had been made. "The astonishing slowness with which useful knowledge concerning these things is gained, in spite of the large number of investigators, is in the most part explained by the great difficulty which is experienced in settling the natural history of these plants, about which even the professional botanists have but very limited knowledge, and of which very incomplete descriptions and delineations exist. Such an investigation demands, therefore, a very greatly extended labor, and the result is very much less profitable than the cultivation of any other subject in pathology. Meanwhile we meet here a special difficulty." (Compare *Virchow's Archiv*, 1880, Bd. xxxix, page 206.) So far as mould and yeast fungi are concerned, the natural history of these parasites, at least the general features, were known. Yet the whole province of those plants latterly classed under the name of schizomycetes, was not only very uncertain, but its conception had undergone such great changes that almost every one turned away from it with aversion. Ehrenberg had only a short time before described these formations as animals, and had classed them with the infusoria. Then it was discovered that all the detailed description of the finer organization of these forms by the great microscopist were erroneous, and for not a few of them it became possible to demonstrate their vegetable character. But the microscopes of that period were very imperfect, pure cultures did not succeed, the modern staining fluids were, as is conceivable, unknown, since the material for the staining of many of them, was not even discovered. Finally such little growths were found in all manner of impure and putrefying substances, giving rise to the popular notion, that every drop of water, every bubble of air contained them by the thousand. Is it a wonder that these things were overlooked, even if they were found?

In support of this I may mention my own position in regard to cholera. On July 31, and August 1, 1848, occurred the first cases of that epidemic which afterward became widespread. The first case was fatal. I found in the intestines numberless vibriones, yet in the blood no foreign elements such as vibriones. In the second case I examined the evacuations, and demonstrated the presence of vibriones and ciliated monads (*Medical Reform*, 1848, No. 5, page 28. *Gesammelten Abhandlungen aus dem Gebiete der offentl. Medicin und Seuchenlehre*, page 128). Then I discussed also the question of the significance of infusoria and remarked that "I took no stock in the diseases caused by infusoria, and as regards cholera, such forms were found only in the evacuations and were in no way characteristic of cholera, but simply indexes to the commencement of putrefaction. The synchronous development of carbonate of ammonia and the roseate hue formed in the masses on the addition of nitric acid demonstrated this" (*Medical Reform*, No. 15, *Ges. Abhandl.*, page 137). An especial support seemed to me to exist for this conception in the fact that the contents of the intestines in the upper part gave an acid reaction, and in the lower part were alkaline, "and here were found the infusoria of putrefaction and not above" (*Medical Reform*, 1849, *Ges. Abhandl.*, page 148). Whether these "infusoria" were identical with the comma bacillis I cannot determine; presumably some of them were present. But an accurate analysis was out of the question at that time, and as is taught by the lines quoted, out of the direction of the theoretical considerations. But the point was remembered, and when, 20 years later, a recent case of arsenical poisoning with choleraic symptoms presented itself, I examined it with reference to this very point. I hoped to find in the nature of the contents of the intestines the means of diagnosis. But the rice water contained in the large intestines showed upon microscopical examination the same composition as in cholera, especially innumerable masses of the smallest bacteria and vibriones, which were identical with the cholera fungi described by Klob and others (*Virchow's Archiv*, 1869, Bd. xlvii, page 525). Thus I remained for another decennium of the same opinion, only emphasizing that what was called in 1848 vibriones, is now described as micrococci or as sphero bacteria, and I said: "Even now I am not convinced of the specific nature of these micro organisms" (*Ges. Abhandl.*, page 513). I refer, not to become tedious, to other parts of my "Ges. Abhandl. aus dem Gebiete der off. Medicin," Bd. ii, page 185, and particularly page 272. (Compare *Virchow's Archiv*, 1868, Bd. xlv, page 280.) In this place I said: "With the smallness of the formations under consideration, and the impossibility of distinguishing them in the present state of our knowledge—nevertheless I cannot subdue the hope that experimental investigations may yet succeed in finding a specific vibrio of cholera. I will therefore not reject the thought of the existence of a cholera fungus. *One may conceive, therefore, that the cholera miasma consists of a fungus ferment for which there are many reasons.* Yet this is still only a bare analogy, a possibility but no confirmed fact." The latest history of the comma bacilli has taught how difficult it is, even with the improved instruments and methods of to-day, to arrive at a definite conclusion, and I think every impartial observer will find it justifiable, when I continue to advise circumspection in the hypothetic extension of the parasitic doctrine. This variation in the inclination to employ this doctrine as the explanation of all infectious diseases dates from the discovery of the bacilli of anthrax by Pollender, Davaine and Brauell (1854-57), the cocci of variola and vaccinia by Keber (1868), and the spirilla of relapsing fever by my former assistant, Obermeier (1873), as I have more precisely explained in my lecture on the progress of military medicine (*Ges. Abh.*, Bd. ii, p. 175, and in *Virchow's Archiv*, 1880, Bd.

lxxix, page 207) With these the first valid examples of defined diseases, caused by schyomycetes, and especially the presence of the disease causing micro organisms in the blood, were furnished, and it can be at once admitted that through these facts a sure and substantial foundation was built for the hitherto very vague hypothesis

There is still very much to be done For a large number, and, indeed, the most frequent, of the infective and contagious diseases, demonstration of the presence of micro organisms is yet wanting, though they are suspected to exist Yet this demonstration is only the first step upon the difficult road towards a knowledge of the disease processes Many pretend not to be aware that by the bare demonstration of a bacterium or a micrococcus little is gained Yet neither pathology nor therapy can be satisfied with it What is the improvement in the treatment of relapsing fever because the spirillum has been found? What influence has the discovery of micrococci in the lymph and the organs had upon the doctrine of vaccination for small-pox? Had we not the successes of Pasteur in the manufacture of diverse protective vaccinæ for different infectious diseases the only practical interest would centre in Listerism, and this, it must not be forgotten, owes its existence more to an ingenious divination than to a strictly purposive scientific investigation Nevertheless, micro organisms occupy the foreground of medical interest, they not only control the domain of thought, but also the dreams of many older and most young physicians The cells seem to be forgotten I cannot abstain from citing a few pungent sentences of a Paris journal, since they give a very spirited expression of this frame of mind "The cellular republic has had its existence Our body is no more a republic of cells, living each one its proper life, often dangerous, through their peculiar characteristics, and through their invading tendencies, to the body which contains them

"This cherished republic was created by the German, Professor Virchow Dethroned is your cellular republic great master She also was accused by pathologic 'tonkinades' (and she yielded to the verdict of the parasitic fashion, 'Down with the cells!') These (the parasites) live their independent existences, infinitely small, yet prolific, with race characteristics, living within the different centres, one off the other They come from the outside, they penetrate almost on a sudden into the organism, ravaging by the right of invasion and of conquest, without regard for parentage or alliance" —*Le Journal Medical Quotidien*, 1885, No 61

The cells were indeed forgotten for a time Many a one who, through the medium of his Abbé Zeiss apparatus, had made the cells invisible, and who perceived nothing but the colored microbes, may have really believed that the cells needed no further consideration But they are nevertheless still existing, and to speak frankly, are, after all, the essential part But their turn will come again when medical men shall have, in some manner, filled the gaps which are still existing in the knowledge of botany

Perhaps this is a little too generally expressed, for, in fact, the same thing is repeated with every new parasitical cause of disease First, the discovery of the parasite , then the investigation of its natural history, then the question, How does it cause the disease? It is only in this third stage of the affair, strictly speaking that we return to pathology, and truly to the same pathology which had obtained previously Nowhere is this so clearly expressed as in the history of phthisis When Koch discovered the tubercle bacillus, many pretended that now all the toilsome labors of the past had become unnecessary —one kind of bacillus, therefore one form of phthisis Tuberculosis of the lungs is identical with cheesy hepatization, glandular tuberculosis with scrofula, etc This beautiful unity has not lasted very long Phthisis of the lungs has remained what it was—a complete process, commencing in very different ways, sometimes in the mucous membrane of the air passages, sometimes in the interior of the alveoli, and sometimes in the parenchyma of the lungs, and giving rise to entirely different products, sometimes simply inflammatory, and then specifically tuberculous ones, and whoever wants to comprehend this complex process must have learned something more than how to stain bacilli The bacillus has advanced the comprehension of the process so little, that one has returned again, after a very short time, to the investigation of predisposition and immunity I was engaged in this investigation a generation ago At the meeting of the Wurzburg Physico medical Society, on February 14, 1852 (*Wurzb Ver* , Bd iii, page 98), I spoke of "the difference between phthisis and tuberculosis," and explained amply the phthisical predisposition This essay is, naturally, long since forgotten, but it is curious to observe how, after the first bacillar excitement, the necessity of the case so quickly again has forced investigation into the same channel which formerly seemed to be the correct one

In this place I desire to show that the knowledge of the bacillus, however necessary it may be for the comprehension of the origin of a disease process, nevertheless does not explain the process itself, nor does it make its special investigation unnecessary This is still more evident in lepra The demonstration of the bacillus lepræ has excluded a whole series of other possible explanations, but a positive progress in diagnosis, prognosis and cure of lepra will not be made until our knowledge of the local affections of lepra has been enriched with something more than the addition of a few bacilli to the lepra cells This relation, to explain which is really the main object of the specific pathological, or more generally expressed, of the medical investigation of these forms of disease, I may call *the battle of the cells with parasitic micro organisms*, or shorter but not quite as correct, with bacteria Apparently two living organisms face one another, the microscopic cells, the vital elements of the body, on the one hand, the still smaller fungi, the lowest plants, on the other Each have their own life, therefore also their own activity and their own strength Which of them is the assailant? What is the manner of its assault? Does the one or the other resist, and through what qualities? Which of them is destroyed? These are questions which ought to be answered. That disease is a battle is an old saying. Even Schultzenstein formulated this by saying "Disease is a battle of life with death." At present we know little more of the character and activity of the cells than of those of the vegetable parasites. But the living reaction of the cells is studied better than the action of the parasites, and the scientific interest, therefore, will for the present lean entirely towards this subject. I defined this question more precisely in a lecture[1] before the Berlin Medical Society, on Feb. 8th, 1871 (*Berliner Klin. Wochenschr.*, 1871, No. 10.). Only this I wish to emphasize, that I distinguished between the effects of the foreign living body as such, and those created by its products, particularly the poisonous substances generated by it. On the other hand, the problem of the near future will be to take up, to a greater extent than has hitherto been done, the investigation of the living cells in regard to their power of resistance and the mechanism of their defense. A very promising commencement has been made by Dr. Metschnikoff in two papers (*Archiv*, 1884, Bd. xcvi, page 177, and Bd. xcvii, page 502), in which he described the reception of the parasites into the interior of the cells, and their further fate, particularly their digestion by the cells. Objections have been raised against this conception, which are entitled to attention. More particularly has the capacity for attack of the intruder as compared with the power of resistence of the cells not received merited attention. But the course taken is unquestionably the correct one. With commendable good judgment Dr. Metschnikoff has taken the initiatory step by the observation of small aquatic animals. They are studied most easily when their conditions of life, particularly their abode in the water, are least disturbed. The smallest sea animals, be they fully developed, or in their larval state, are the most convenient objects for this study, and it is to be hoped that much further study will be done in this direction.

[There exists a very strong tendency to undermine and discredit the cellular theory of body construction, and as a legitimate offspring of this, cellular pathology, so that the halt called by Professor Virchow seems very opportune to those who, like the translator, believe in this cellular theory, and applied to the utmost limit to the developmental theory, at that. It seems quite remarkable that many busy hands should already be employed in pulling down this beautiful and most useful structure of Schleiden, and Schwann, and Virchow, when a great number of the medical profession, and particularly on this continent, have not even grasped the cellular theory in its diverse applications, so that few are capable of following with full understanding the pros and cons of the question. This is substantiated again, as often before, by the paper of Dr. Elias Metschnikoff, of Odessa, to which Prof. Virchow refers. Though pregnant with the most important thoughts concerning both the cellular theory and the parasitic hypothesis, no journal in this country has as yet mentioned it (if so, it has eluded my search), though the first paper appeared in the *Archiv* in May, 1884. In these papers Dr. Metschnikoff describes his observations of a disease in the body of the Daphnia magna (Whirling dun), caused by the presence of a yeast fungus, which he names monospora bicuspidata. The fungus propagates itself by gemnation and spore formation. The latter, the spores, are contained one at a time in its ascus, and are double pointed, spindle shaped, hence the name of the plant. Metschnikoff has followed all the phases of the life history of this fungus in the body of the daphnia, from its germinal inception (spore) to its death, or that of its host. And the reader who follows him carefully in his lucid descriptions is forced to conclude that he presents him with a battle for the survival of the fittest,—in this instance the fungus on the one side, the phagocytes (eating cells) on the other, now the former, now the latter, triumphant. With the victory of the fungus, the animal perishes, with the triumph of the phagocytes (white blood corpuscles and amœboid cells of the connective tissue), the animal survives. So long as the daphnia, *i. e.*, its phagocytes, retain their vigor and only spores find their way into its tissues from its alimentary canal, the white corpuscles surround and take up the spores and *digest* them, *i. e.*, kill them. But when from any cause the fungus matures and commences to form conidia and spore bearing asci in the body of the daphnia, this can no longer resist its enemy and it invariably perishes.

"From this description one may perceive," says Dr. Metschnikoff, "that the infection and disease of our daphnias is a battle between living creatures, the fungi and phagocytes. The former present themselves to us as lowly organized unicellular plants, the latter, on the other hand, as the lowest tissue elements which present the greatest similarity to the simplest organisms (particularly amœbæ, rhizopodes, etc.). The phagocytes retaining their original character of intracellular food reception, act through it as the exterminators of the parasites, and appear, therefore, as representatives of the long-since known healing power of nature, which was first placed by Virchow into the tissue elements. The fundamental thought of the cellular theory of this master is fully exemplified in the history of this daphnia disease, since the main part is taken by the independent tissue elements."

He continues to form an analogy, and with good reason, between the occurrences in the disease of the daphnia and tuberculosis, and concludes "that also in tuberculosis, against the cause of the disease, a battle of the phagocytes rages, through which the organism often for a long time resists, and, in some instances, conquers. In regard to lepra he says: "The destruction of the bacilli in the interior of the cells, which accompanies the formation of vacuolæ, points plainly towards a digesting reaction of the lepra cell. The whole description of Neisser agrees with the demonstrable side of the phenomena of intra cellular digestion as has been observed in infusoria, rhizopoda and the cells of metozoa" Finally he says "It is known that pus corpuscles, after the retention for some time of a body eaten by them, die, when they are taken up by another leucocyte, which devours both dead corpuscle and foreign body"

---

[1] I refer those who are interested *in this subject* to that lecture which was printed in my Gessammelten Abhandlungen aus dem Gebiete der offentlichen Medicin."

One suggestion is particularly worthy of consideration he supposes that the successful battle of the phagocytes with the vaccination virus—a brood of weaklings prepares these scavengers of the body, the *vis medicatrix naturæ* of antiquity—to do battle with the vigorous bacilli of anthrax, variola, chicken-pox, etc, enemies not enfeebled by modern methods A rather new but not pleasing proof of the old maxim, "that practice makes perfect" The phagocytes first attack the weak bacilli of the vaccination fluids and finally war with the genuine and vigorous plants —often, but not always with success Now this question of the cause of disease by parasitic plants must, of necessity, remain a very vague affair, as long as prominent features, concerning not the parasites, but the diseased person or organ, are entirely overlooked For example The modified card, issued by the committee on collective investigation of disease, within reach of Virchow himself, perpetrates the following

Tuberculosis pulmonum —To the questions about 1, Heredity, 2, Contagiousness, 3, Cure and 4, *Development from pneumonia*" Under this fourth caption we read

"4 To the development of *phthisis* from genuine pneumonia.

(c) When developed the first symptoms of *tuberculosis*, and what were they?"

What does the committee mean by this kaleidoscopic throwing together of terms? Do they pretend to say, and in the face of our overwhelming clinical data, that tuberculosis pulmonum and phthisis pulmonum are identical terms and denote identical processes? Do they, in all seriousness, ask whether tuberculosis pulmonum ever develops from inflammation of the lung? If so, let them settle this question first before they go any farther To those who have *studied* the writings of Virchow, Rindfleish and others, these things have become convictions—we know that it is out of the nature of things for idiopathic (croupous) pneumonia, for such is here mentioned, to change into or have developed from it—tuberculosis Perhaps the micrococci of Friedländer change in Germany into the bacilli of Koch when required! Have not clinicians of some experience seen cases of phthisis pulmonum, *post mortem*, where with the greatest care and search no tubercles could be detected, nor during life bacilli of Koch in the sputa—could any stretch of the imagination call such a case one of tuberculosis?

Tuberculosis may be grafted on a lung, sick with catarrhal or croupous pneumonia, and indeed this seems the more probable from the researches of Dr Metschnikoff, which also partially explain why catarrhal should be more likely to be followed by tuberculosis than the other forms of pneumonia Of course I am not speaking of that form of so called catarrhal pneumonia which should properly be called scrofulous, caseous or tubercular pneumonia But this condition of things is far from being identical with the development of an infective disease from a purely inflammatory process Again, if the inflammatory process is followed by destruction and removal of lung tissue, resulting in cavities, thus presenting the clinical picture of phthisis pulmonum, it is not related to tuberculosis, except as tuberculosis is grafted on the process, either on the initiatory one, the inflammatory, or the phthisical, the destructive terminal one This must always take place by infection, auto infection or otherwise with the bacillus or poison of tuberculosis A little more histology—a little more cellular pathology—a great deal more work like that of Dr Metschnikoff, and a little less of confusion of terms and processes, and our work will be more scientific and profitable TRANSLATOR]

STATE MEDICINE.

THE ILLINOIS ANATOMY ACT

The following important law was passed by the Illinois Legislature during its recent session

SECTION 1 WHO MAY DELIVER AND WHAT BODIES MAY BE DELIVERED FOR SCIENTIFIC STUDY, ETC *Be it enacted by the People of the State of Illinois, represented in the General Assembly* That the superintendents of penitentiaries, houses of correction and bridewells, wardens of hospitals, insane asylums and poor houses, coroners, sheriffs, jailors, city and county undertakers, and all other State, county, town and city officers, in whose custody the body of any deceased persons, required to be buried at public expense, shall be, shall give permission to any physician or surgeon, (a licentiate of the State board of health), or any medical college or school public or private, of any city, town or county, upon his or their request therefore to receive and remove free of charge or expense, after having given proper notice to relatives or guardians of the deceased, the bodies of such deceased persons to be buried at public expense, to be by him or them used within the State, for advancement of medical science, preference being given to medical colleges or schools, public or private, said bodies to be distributed to and among the same, equitably, the number assigned to each, being in proportion to the students of each college or school *Provided however*, that if any person claiming to be, and satisfying the proper authorities that he is of kindred to the deceased, shall ask to have the body for burial, it shall be surrendered for interment *And provided further*, that any medical college or school public and private, or any officers of the same, that shall receive the bodies of deceased persons for the purpose of scientific study, under the provisions of this act, shall furnish the same to students of medicine and surgery, who may be under their instruction, at a price not exceeding the sum of five dollars for each and every such deceased body so furnished

SEC 2 HOW BODY TO BE USED—BOND TO BE GIVEN, ETC Any physician or surgeon, (a licentiate of the Illinois State Board of Health) or any medical college or school, public or private, before receiving any dead body or bodies, shall give to the proper authority, surrendering the same to him or them, a sufficient bond that said body or bodies shall be used only for the promotion of medical science within this State, and whoever shall use said body or bodies for any other purpose, or shall remove the same beyond the limits of this State, and whosoever shall sell or buy any such body or bodies or shall traffic in the same, shall be deemed guilty of a misdemeanor, and shall, on conviction, be fined in a sum of not less than one hundred dollars, and be imprisoned in the county jail for a term not less than thirty days nor more than one year, the fine accruing from such conviction, to be paid into the school fund of the county where the offense shall have been committed

Sec 3 Penalty for officer refusing to deliver body, etc Any officer refusing to deliver the remains or body of any deceased person when demanded in accordance with the provisions of this act, shall pay a penalty of not less than fifty dollars, nor more than one hundred dollars for the first offense, and for the second offense, a penalty of not less than one hundred dollars, nor more than five hundred dollars, and for a third offense, or any offense thereafter, the penalty of not less than five hundred dollars, or to be imprisoned in the county jail not less than six nor more than twelve months, or both at the discretion of the court, such penalties to be sued for by the health department, as the case may be

Sec 4 Duty of professors, etc, to bury bodies, etc It shall be the duty of preceptors, professors and teachers, and all officers of medical colleges or schools, public or private, who shall receive any dead body or bodies, in pursuance of the provisions of this act, decently to bury, in some public cemetery, or to cremate the same in a furnace properly constructed for that purpose, the remains of all bodies, after they shall have answered the purpose of study aforesaid, and for any neglect or violations of the provisions of this act, the party or parties so neglecting, shall on conviction, forfeit or pay a penalty of not less than fifty dollars, nor more than one hundred dollars, or to be imprisoned in the county jail not less than six nor more than twelve months, or both, at the discretion of the court, such penalties to be sued for by school officers, or any person interested therein, for the benefit of the school fund of the county in which the offense shall have been committed

Sec 5 Repeal An act entitled "An act to promote the science of medicine and surgery in the State of Illinois," approved February 16, 1874, in force July 1, 1874, is hereby repealed

FOREIGN CORRESPONDENCE

LETTER FROM BERLIN

(FROM OUR OWN CORRESPONDENT)

Rag Disinfection—Laparotomy for Rupture of the Uterus—Hay Bacillus and Bacillus Anthracis

Some weeks ago, without the least knowledge on my part that such an appointment was contemplated, and without any definite conception of the regulations of the Treasury Department governing the exportation from Germany to the United States of old rags, I was requested by the Consul-General to assume the duties of inspector. The circular issued by the Hon H McCulloch, Dec 22, 1884, prescribed the following processes, either of which will be considered a satisfactory method of disinfection of old rags, and will entitle them to entry and to be landed in the United States upon the usual permit of the local health officer, viz

1 Boiling in water for two hours under a pressure of fifty pounds per square inch 2 Boiling in water for four hours without pressure 3 Subjection to the action of confined sulphurous acid gas for six hours, burning one and a half or two pounds of roll brimstone in each 1,000 cubic feet of space, with the rags well scattered upon racks 4 Disinfection in the bale by the means of perforated screws or tubes, through which sulphur dioxide, or super heated steam at a temperature of not less than 330° F, shall be forced under a pressure of four atmospheres for such a period as is sufficient to insure thorough disinfection

The chief baling and shipping stations in North Germany are Konigsberg, Dantzig, Stetten, Riesa, Berlin, Hanover, Harburg and Hamburg The chief firms controlling this business are Lewy Gebruder, of Konigsberg and Berlin, Lewy and Strich, of Konigsberg and Berlin, Gebruder Salomon, of Hanover and Harburg, and Wertheim, of Hamburg This latter gentleman is agent for Germany of a patent disinfecting arrangement erected in New York Harbor, which, so far, meets with little favor Merchants here will not ship rags to be disinfected in New York, because, among other reasons, of the greater expense, so the company endeavors to force patronage by untruthful statements of foreign inspection, or by sensational reports of the rapid advance of cholera The rags shipped from these ports are all North of Germany or Russian rags, quite clean and free from infection In their disinfection they lose their dust, which is a gain to hygiene, though a loss to the merchants, as it reduces the weight There has not been a case of cholera in this region of country for over eight years, and there have been but very few instances of malignant dysentery Every year, from North Germany alone, there are shipped to the United States about one hundred thousand bales of rags

The sulphur process is in favor here In Berlin, Hanover and Harburg I have made use of the following plan A large room in the warehouse is set apart as a disinfecting room In the centre is a well of fireproof stone resting on a floor of the same material about six feet square, the sides being four feet high In the middle is a large graphite pot for the sulphur, and the whole is covered over with an iron grating The windows and doors are all tightly closed The rags are scattered about on the floor and racks, and are kept in the fumes for five hours In the ceiling is a large ventilator, which is opened from the outside by a string and pulley

This is opened at the expiration of the disinfection In Konigsberg I utilized an old sugar house with a chimney 120 feet high There was one large room where the rags were scattered about, and a small room adjoining, in which a special furnace of brick was built for the burning of sulphur Four large tubes perforated the partition between the two rooms, through which the fumes of the sulphur are blown This is a very practical and safe arrangement The large chimney was used as a ventilator About seventy pounds of sulphur every day are consumed by each of the two firms exporting from Konigsberg Working full force, and keeping late hours, each firm in Konigsberg, if pressed, could disinfect and press nearly 300 bales per diem In this city more rags are baled and shipped than from any other port in Germany—perhaps from any other two cities The business here is almost entirely controlled by Levy Gebruder and Levy and Strich Berlin does but a small business, averaging, perhaps, forty bales per diem If the market were active, the same two firms, who also control the business here, could bale about 150 bales each per diem Since my appointment the Berlin firms have only disinfected about 2,700 bales, burning on the average fifty pounds of sulphur for each twenty or twenty-five bales, and disinfecting sometimes twice in the day In Hanover and Harburg the Gebruder Salomon have extensive facilities, and, if necessary, could bale in the two places about 350 to 500 bales per diem I have inspected about 700 bales from each of these cities

Now the question naturally arises—How is it possible for one inspector to give his personal attention to places so widely separated from each other? The answer is a simple one At no one city is the business constant It is always intermittent Little is done at Berlin, and that irregularly At Konigsberg it is also spasmodic While disinfection is going on in Berlin I stop it at Konigsberg By special permission of the Consul General, and as a favor to the merchants, I went to Hanover and Harburg The quantities here being small, we finished rapidly by working full force and long hours I do not suppose that any scientific man claims that the sulphur process has any effect as a germicide upon the bacillus of Koch Bacilli are killed by drying but it is necessary to bear in mind that they must be exposed to the drying process in thin layers At the temperature of boiling water they are invariably killed, but not *their spores* Even heating them from half an hour to several hours at a temperature of 55° or 60° C kills them, but not their spores Freezing has no effect upon the spores "The spores represent the seeds, capable of retaining life, and of germinating into bacilli, even after what would appear the most damaging influences (that is, damaging to all other kinds of organisms, and to the bacilli themselves), such as long lapses of time, drying, heat, cold, chemical reagents, etc Spores retain the power to germinate into bacilli after the lapse of long periods, and there is no reason to assume that these periods have any limits, it makes no difference whether they are kept dry or in the mother liquid The great resistance of spores high temperatures, to acids or other s due to this, that the substance of each veloped in a double sheath—an intern probably of a fatty nature, and an ext probably of cellulose Both are bad con heat"—(Klein)

While it is undoubtedly true, then, tha tion is valueless as a preventive of cho equally true that its value as a hygienic me not be overestimated All rags comin United States for the next few years shou infected, because this process does act as cide in the micro organisms of typhoid (?)— this is not a specific organism, but a migr from the degenerated intestine—small pox, d dysentery, etc , and just in proportion as t fection is thoroughly done, so much the be the health of our entrepôts be But why this about cholera? Even in Spain the disease sumed but small proportions, and Spain is miles removed from Berlin The health of Germany is perfect, and if it be true that r convey the potent cholera bacillus, it seems s that the many hundreds of men, women and c who are engaged here in assorting, baling, a ranging, who daily respire for many hours the atmosphere, and whose bodies are in a ripe tion for infection, never show any symptoms disease It is natural to suppose that the in dence of rag infection would be manifested persons of those here in Germany who are en in handling them Does the bacillus (or the s thereof) carry a potency for cholera within its m scopic envelope?

I lately saw a laparotomy for rupture of the ut which was successful in regard to the mother operation was done, and very properly done, a two hours after the accident The abdominal ca the uterine cavity and vagina were thoroughly w out with warm carbolized water, the stream kept up for ten or fifteen minutes The intest were thoroughly cleansed, and drainage establis *through the vagina* The rent in the uterus sewn up, and the abdominal wound closed danger in these cases is not from the operation which is not any more difficult or hazardous t many similar abdominal sections for uterine tum Indeed, it is not in itself as severe as a supra-vag hysterectomy The mischief has already been do by the rending of the uterine tissue The nerv system has received a profound shock, which exaggerated as the hæmorrhage continues An i mediate operation is the only hope The dang are all tenfold intensified by waiting Adventitio sacs will form, plastic adhesions will prove troub some, and the system generally will appreciate th septic changes engendered by the decomposing mas within the abdomen A late operation can *never* result favorably, all the pathological change against it If seen early enough, even tho fœtus may have escaped *per vias naturale* otomy is the best safeguard against septicæmi diagnosis of an impending rupture of the of the Illinoi such immense difficulty, and seems to college or scal, that it seems difficult to believe it is any dead l Lusk asserts that it can be fore-authority,, and in some instances prevented This sufficientnement of diagnosis not as yet reached by only for obstetricians, and not admitted by German State, a

any othold is having some good results from Saen the limiethod of Caesarian section, and prefers this buy anvative plan to the Poiro Muller He has had same, sases, all of them successful

shall, oHans Buchner ("Ueber die Experimentale than ozung des Milzbrandcontagiums, etc") says countye has succeeded in transforming the common more is of hay infusion, the hay bacillus, into the conviax bacillus, and that he has done this by suc-countre cultivation of bacillus anthracis under *con*

Sec *varation of the nutritive material* Morpho LIVERally considered, both of these forms come under remaiead of Cohn's bacillus subtilis Lately I have mand very carefully through all of Buchner's work, shall I have entirely failed to reproduce his results more bacillus anthracis is non motile Ewart's asser-and that they became motile is not borne out by one e elaborate experiments Koch regards Buch-dolls statements that successive cultivations of the afteillus anthracis at 35° to 37° assumes the morpho-lars, al and physiological characteristics of hay bacil-than , a complete error It will be a serious matter discrete animal kingdom if Buchner's opinions shall for bubstantiated by other observers H R B

MESTIC CORRESPONDENCE

EMIC DYSENTERY AT PORTER, INDIANA

OR JOURNAL AMERICAN MEDICAL ASSOCIATION

ear Sir —In as much as I have many cases er treatment at Porter, Indiana, I deem it expe-t to give you my observation of the existing epi-of suc The malady raging is *epidemic dysentery* of t e Aug 3, I have had, at Porter, 28 cases of negentery under my care Two of these cases, Mrs alty o B——, aged 20 years, and Peter S——, aged hunyears, are of a typhoid type,—prognosis doubt-jail, the other cases, 26 in number, are improving or A rumor has gained currency that the epidemic at to Irter was caused by the eating of diseased meat, estrchased of a certain butcher of Chesterton Indi-thea Of the 28 cases under my care, not one had coten meat purchased from said butcher, and in any instances, no meat had been eaten for several preeks

St Porter, Indiana, is situated on a low flat tract of found, and is not blessed with any kind of sewerage or drainage Ditches run parallel with the side-walks of the several thoroughfares,—these ditches have no outlet The main alley of the town is a mass of garbage and filth, the majority of the privies along this alley are overflowing As a rule, the well in each yard is from 10 to 20 feet from the alley and privy The floors of the houses set on the damp ground and, in many instances, six to eight people are crowded into two or three rooms

For three weeks previous to Aug 1, Porter had been subjected to sudden vicissitudes of temperature from a high to a low range, for the seven days previous to Aug 1, the climate resembled a tropical one, and was followed by a heavy, drenching rain of 24 hours duration, making a fall of about 4½ to 5 inches of water The lack of the proper sewerage and drainage, the bad sanitary condition of the town, the continued high temperature, followed by a heavy rain fall, the swampy country, the damp and cold crowded houses, the polluted well water, the noxious air,—all were conducive to miasmatic diseases of the dysenteric type After a thorough investigation, I have failed to trace a single one of my 28 cases to tainted meat Yours truly,

ALEX J MULLEN, JR M D

Michigan City, August 10, 1885

BOOK REVIEWS

A SYSTEM OF PRACTICAL MEDICINE BY AMERICAN AUTHORS EDITED BY WILLIAM PEPPER, M D, LL D, etc Assisted by LOUIS STARR, M D, etc Volume II General Diseases (continued) and Diseases of the Digestive System Philadelphia Lea Brothers & Co, 1885

What was said of the general character of this work, in the notice of the first volume, need not be repeated here Indeed, in order to show the value of the second volume, it is scarcely necessary to do more than give a list of the various subjects treated of, with the names of the writers

The first 254 pages of the work are what may be called a continuation of the first volume on General Diseases The volume opens with an article on Rheumatism, by Prof Howard, of McGill University, and is followed by one on Gout, by Dr W H Draper The other articles on general diseases are Rachitis, by A Jacobi, Scurvy, by Philip S Wales, Purpura, by I Edmondson Atkinson, Diabetes Mellitus, by James Tyson, Scrofula, by John S Lynch, and Hereditary Syphilis, by J William White With such an array of most excellent articles by thoroughly competent writers it is difficult to select one or two that seem worthy of special mention Those on Diabetes and Hereditary Syphilis, however, seem more worthy of special mention, if any are Professor Tyson's article, though occupying only thirty-six pages, seems to leave nothing unsaid that could possibly be of benefit to the practitioner who has under his care a case of diabetes, and it is especially valuable for the remarks on the tests for sugar and the bill of fare for diabetics The writer is deservedly known for his thorough urological work, and the diet table for diabetics is alone worth the price of the work

Dr J William White discusses the subject Hereditary Syphilis in 64 pages, with an array of references that is marvelous as regards completeness, there being not less than two hundred and ten Of the article itself it need scarcely be said that it is as complete as an article on this subject could possibly be

In the second part of the book, on Diseases of the Digestive System, are thirty articles Those

This is opened at the expiration of the disinfection In Konigsberg I utilized an old sugar house with a chimney 120 feet high There was one large room where the rags were scattered about, and a small room adjoining, in which a special furnace of brick was built for the burning of sulphur Four large tubes perforated the partition between the two rooms, through which the fumes of the sulphur are blown This is a very practical and safe arrangement The large chimney was used as a ventilator About seventy pounds of sulphur every day are consumed by each of the two firms exporting from Konigsberg Working full force, and keeping late hours, each firm in Konigsberg, if pressed, could disinfect and press nearly 300 bales per diem In this city more rags are baled and shipped than from any other port in Germany—perhaps from any other two cities The business here is almost entirely controlled by Lewy Gebruder and Lewy and Strich Berlin does but a small business, averaging, perhaps, forty bales per diem If the market were active, the same two firms, who also control the business here, could bale about 150 bales each per diem Since my appointment the Berlin firms have only disinfected about 2,700 bales, burning on the average fifty pounds of sulphur for each twenty or twenty-five bales, and disinfecting sometimes twice in the day In Hanover and Harburg the Gebruder Salomon have extensive facilities, and, if necessary, could bale in the two places about 350 to 500 bales per diem I have inspected about 700 bales from each of these cities

What was said of the general character of this work, in the notice of the first volume, need not be repeated here Indeed, in order to show the value of the second volume, it is scarcely necessary to do more than give a list of the various subjects treated of, with the names of the writers

The first 254 pages of the work are what may be called a continuation of the first volume on General Diseases The volume opens with an article on Rheumatism, by Prof Howard, of McGill University, and is followed by one on Gout, by Dr W H Draper The other articles on general diseases are Rachitis, by A Jacobi, Scurvy, by Philip S Wales, Purpura, by I Edmondson Atkinson, Diabetes Mellitus, by James Tyson, Scrofula, by John S Lynch, and Hereditary Syphilis, by J William White With such an array of most excellent articles by thoroughly competent writers it is difficult to select one or two that seem worthy of special mention Those on Diabetes and Hereditary Syphilis, however, seem more worthy of special mention, if any are Professor Tyson's article, though occupying only thirty-six pages, seems to leave nothing unsaid that could possibly be of benefit to the practitioner who has under his care a case of diabetes, and it is especially valuable for the remarks on the tests for sugar and the bill of fare for diabetics The writer is deservedly known for his thorough urological work, and the diet table for diabetics is alone worth the price of the work

Dr J William White discusses the subject Hereditary Syphilis in 64 pages, with an array of references that is marvelous as regards completeness, there being not less than two hundred and ten Of the article itself it need scarcely be said that it is as complete as an article on this subject could possibly be

In the second part of the book, on Diseases of the Digestive System, are thirty articles Those on Diseases of the Mouth and Tongue, of the Tonsils, of the Pharynx, and of the Œsophagus are by Dr J Solis Cohen Dr Samuel G Armor writes on Functional and Inflammatory Diseases of the Stomach, Professor W H Welch on Simple Ulcer of the Stomach, Cancer of the Stomach, Hemorrhage from the Stomach, Dilatation of the Stomach, and Minor Organic Affections of the Stomach (including Cirrhosis, Hypertrophic Stenosis of Pylorus, Atrophy, Anomalies in the Form and Position of the Stomach, Rupture, Gastro malacia) The six articles on Intestinal Indigestion, Constipation, Enteralgia, Acute Intestinal Catarrh, and Cholera Morbus are by Prof W W Johnston, of Washington Dr J Lewis Smith contributes the article on Intestinal Affections of Children in Hot Weather, Dr Philip S Wales that on Pseudo membranous Enteritis, and Professor James T Whittaker those on Dysentery, Typhlitis, Perityphlitis and Paratyphlitis, Intestinal Ulcer, and Hemorrhage of the Bowels The article on Intestinal Obstruction is by Dr Hunter McGuire, on Cancer and Lardaceous Degeneration of the Intestines by Dr Edmondson Atkinson, and that on Diseases of the Rectum and Anus by Drs Thomas C Morton and Henry M Wetherill Profesosr Leidy contributes that on Intestinal Worms, Professor Roberts Bartholow that on Diseases of the Liver, and the Assistant Editor that on Diseases of the Pancreas The long and very valuable article on Peritonitis by Prof Alonzo Clark will be read with more than ordinary interest, especially by those who have, for many years past, listened to his lectures on this subject The concluding article, Diseases of the Abdominal Glands (Tabes Mesenterica), is by Dr Samuel C Busey

We see no reason to do otherwise than reiterate the very favorable opinion expressed of this work when the first volume was noticed in the Journal The work is in the highest sense American, a careful reading of the articles will show that authors have attempted to say what was necessary in the fewest words without being unduly terse Certainly in the two volumes that have thus far appeared there is nothing of that tiresome verbosity and wandering from the subject that is so common in similar works from the Continent of Europe The index—one hundred and eighteen pages—seems to be quite complete

ASSOCIATION ITEMS

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with Five Dollars, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly Journal of the Association will be forwarded for one year

Richard J Dunglison, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

State Medical Society of Virginia —The Medical Society of Virginia, will convene at Alleghany Springs, Montgomery Co, Virginia, on Tuesday, September 15 The Fellows and Delegates will be guests of the Alleghany Springs Management Liberal rates have been offered by the railroads of the State, and a large attendance is expected The programme of the meeting will be more fully detailed in a subsequent issue of the Journal

---

The Mississippi Valley Medical Society will meet at Evansville, Ind, on September 8, 9, and 10, 1885 Railroads will return those attending at one third rates Hotels, $1 50 to $2 00 per day This was formerly the Tri State Medical Society For further particulars address Dr A M Owen, Evansville, Indiana

---

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 8 1885 TO AUGUST 14 1885

Capt Thos F 'Ayfull, Asst Surgeon retired from active service Aug 10, 1885 (S O 181, A G O Aug 10, 1885)

First Lt A R Chapin, Asst Surgeon, granted one month's leave, to take effect when services can be spared by Comd'g Gen'l Dept Mo, with permission to apply for one month's extension (S O 179, A G O Aug 6, 1885)

First Lt Philip G Wales, Asst Surgeon (Ft Couer d'Alene, Idaho), ordered for temporary duty at Boise Barracks, Idaho (S O 130, Dept Colo, Aug 1, 1885)

APPOINTMENT

William P Kendall, to be Asst Surgeon U S Army, with the rank of First Lieutenant, to date from Aug 12, 1885

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY, DURING THE WEEK ENDING AUGUST 15 1885

Beyer, H G, Passed Asst Surgeon To attend the meeting of the "American Association for the Advancement of Sciences," at Ann Arbor, Mich, and at conclusion of meeting to resume duty at the Smithsonian Institute

Boyd, John C, Passed Asst Surgeon From Navy Yard, at Washington, D C, to special duty at Bureau of Medicine and Surgery, Washington, Navy Department

Lippincott, J C, Passed Asst Surgeon To Navy Yard, at Washington, D C, as relief of Passed Asst Surg Boyd

Owens, Thomas, Asst Surgeon From special duty at Bureau of Medicine and Surgery, Navy Dep't, and waiting orders

Sayre, J S, Asst Surgeon From U S R S "Independence" to Naval Hospital, Mare Island, Cal

THE SIMILARITY OF ELECTRIC AND NERVE FORCES[1]

BY JOHN J CALDWELL, M D,

OF BALTIMORE MD

In the torpedo the body is somewhat oval and rounded Our native species, found mostly in winter, especially on the low, sandy shores of Cape Cod is Torpedo occidentalis (Storer) Its batteries and nerves are substantially as in the European species The electrical organs are constructed on the principle of the Voltaic pile, consisting of two series or layers of hexagonal cells, the space between the numerous fine transverse plates in the cells filled with a jelly-like, trembling mass, each cell representing, so to speak, a Leyden jar There are about 470 cells in each battery, each provided with nerves sent off from the fifth and eighth pairs of nerves The dorsal side of the apparatus is positively electrical, the ventral side negatively so The electrical current passes from the dorsal to the ventral side When the electrical ray is disturbed by the touch of any object, the impression is conveyed by the sensory nerves to the brain, exciting there an act of will which is conveyed along the electric nerves to the batteries, producing a shock The benumbing force is lost by frequent exercise, being regained by rest, it is also increased by energetic circulation and respiration As in muscular exertion, the electrical power is increased by the action of strychnine (Owen)

Marey has quite recently made interesting experiments on the torpedo, examining the discharge of the fish with the telephone Slight excitations provoked a short, croaking sound Each of the small discharges was composed of a dozen plexus and pulsations, and lasting about one fifteenth of a second The sound from a prolonged discharge, however, continued three or four seconds, and consisted of a sort of groan, with a tonality of about *mi* (165 vibrations), agreeing pretty closely with the result of "graphic experiments" Marey has also studied the resemblance of the electrical apparatus of the electrical ray or torpedo and a muscle Both are subject to will, provided with nerves of centrifugal action, have a very similar chemical composition, and resemble each other in some points of structure A muscle in contraction and in tetanus executes a number of successive small movements or shocks, and a like complexity has been proved by M Marey in the discharge of the torpedo —(Packard, Zoology)

Malapterurus electricus (Lacepede), of the Nile, is electrical, the electric cells forming a layer directly beneath the skin, and enveloping the whole body except the head and fins The cells are minute, lozenge shaped, about one and a half millimetres in diameter They are supplied by a nerve from the spinal cord The shock is comparatively feeble, but suffices for defence, the fish being protected by its electrifying coat as the hedge-hog by its spines (Owen) One of the lowest teleosts, the electrical eel (gymnotus electricus), of South America, is two metres in length, and is characterised by its greatly-developed electrical batteries These are four in number, situated two on each side of the body, and together form nearly the whole lower half of the trunk The plates of the cells are vertical instead of horizontal as in the torpedo, while the entire batteries, or cells, are horizontal instead of vertical as in the electrical ray The nerves sent to the batteries of the eel are supplied by the ventral branches of about two hundred pairs of spinal nerves

In the torpedo there are about 470 cells in each battery This is one of the lowest orders of vertebrates, and therefore the battery construction is simple, the discharges resembling more those from a charged Leyden jar The machine remains at rest to be re charged before another manifestation of power As we ascend, the organism becomes more complex, and in the higher fishes and reptilia and lower mammals the electric apparatus resembles more dynamic electricity, whilst in chimpanzee and gorilla we have Faradic electricity, and, lastly, in man the phenomena require a combination of the different manifestations of this force Hence we have discharge as from a Leyden jar when we knock a man heels over head, whilst in reasoning we employ, or bring into relation, or co ordinate all of the different arrangements, resulting in magnetico-statico dynamic force—ratiocination (S)

As I have contended for years past, it is apparent, from the close analogy of electricity to nerve force, that this agent embraces a wide range of morbid conditions Through the nervous cords which act as conductors, every part of the animal economy can be reached In this way secretion and elimination of morbid products may be promoted, and the organ or apparatus restored to healthy action The three great forces of nature are heat, light, and electricity These are the forces under whose influence vegetation is produced Heat and moisture cause the germ of life in seed to awaken, the materials stored up for the use of the embryo undergo change, both chemical and mechanical, so as to be fit for appropriation The architecture of the plant begins A spire shoots up from the bud, under the influence of the sun's light, the food afforded by the atmosphere is appropriated Forces are active at the root, forces are active in the blade There is no doubt, in my opinion, that electricity is one of the active forces which contribute to plant growth We have all the conditions of its generation—heat, moisture, unequal heating of different mineral substances, causing thermo electricity We also have chemical action It is impossible to draw a line of demarcation between vegetable and animal structure, and I doubt not that heat, light and electricity are the physical forces under which animal structure is built up The light of the sun is as necessary to the health and vigor of the animal as of the vegetable kingdom Indeed, as already stated, the two shade into each other so as to render it impossible to say where the vegetable ceases and the animal begins Electricity, being one of the forces which contribute to the animal organism, is necessary to functional health

ELECTRICAL FORCE IN MAN AND NATURE

All phenomena of the organic or inorganic world are now being interpreted in the terms of matter, motion and force The pilot idea of the doctrine of evolution to day is that everything proceeds from the simple to the complex, and that back of all the manifestations of matter and of mind there lies "unity of force" It is this acting, living, persistent principle which constantly sits at the loom of time, and arranges the position and the texture of the threads that make up the web of things This ancient weaver called "Force" has received many different names When it works among molecules we call it cohesive attraction When it works among the ultimate atoms, building them up into the delicate and beautiful crystals we call it the crystallizing forces When engaged in uniting kindred atoms we call it chemical force, or chemical affinity Our meaning, however, is sufficiently indicated without further extension of the list of forces

Nature delights in prodigality of results, but she is parsimonious in the number of her working powers Given a little matter and motion and she will construct a world The lines of force radiate in all directions, always acting, always persistent Difference of result is but the product of the same force differently conditioned A tree and a mammal betray the same parent force In the ultimate analysis we reach simplicity of cause and "unity of force"

Perhaps one of the most impressive instances of the play of force is to be seen in the phenomena of light Light is but a result of the rapid oscillations of the ether waves Hundreds of millions of these waves strike the retina before we are conscious of the sensation of light How this sensation is translated into consciousness is a mode of force of which we know nothing One fact, however, has been determined, viz that color is a result of motion Less rapid oscillations are required to produce in us the sensation of the red in the spectrum than o the violet Electric light, which is the most intense of all light, is but a product of exalted motion A certain degree of motion produces sound, this motion increased produces heat, a further increase produces all the colors of the spectrum in their regular order Still exalting this motion, we obtain electric light

The theory of wave motion in the ether had its origin in the wave motion of water and atmosphere The ear sustains the same relation to sound that the eye does to light There is a close analogy between the harmony of sound and the harmony of color The rhythm of sound has its unvarying conditions in reference to the human ear Atmospheric vibrations, when they exceed a certain number per second, lose their individuality, and become merged into a hum of indistinct sound The auditory nerve is finely adapted to take in the whole range of the gamut Sounds, higher or lower, in either direction, cease to be distinct

It remains to say a word in reference to the more special manifestations of force The human system supplies the most appropriate example From the persistence of force we can but conclude that between the mind and body there is the closest relation, sensation, thought, and our most involved sentiments imply the destruction of waste of the gray tissue of the brain molecules This waste is only another name for one mode of the "play of force" In a word, man, as he is, is but a product of force, acting, in the first instance, on a germ hardly microscopic, and mind, with all its wonderful and complicated powers, is evolved from the simplest beginnings A Raphael or a Newton are evolved, in common with the lowest orders of animal life, from the product of the same force, controlled and governed by the same law, which had its fitting conditions and relations Want of harmony in these, as we before remarked, implies want of harmony in result A healthy mind, healthy morals and a healthy religion are the resultants of the unimpeded action of force

THE ADVANCE OF MEDICAL SCIENCE

A knowledge of the brain and of the network of the nervous system is the essential to every educated physician, who would minister to a body, or to a mind diseased The ability to maintain a proper medium, through the exaltation or depression of nerve power is requisite to him who would understand correctly the nervous system Her path to universal empire, will continue to be, as it is now, dotted all along with rejected theories She is now making rapid strides, and has indeed become an ocean of truth Let us keep abreast, at least, of that portion of its mighty tide which is now carrying the science of medicine beyond its ancient land-marks, enriching it with new truths Just how electricity acts as a therapeutic agent, no experimenter has satisfactorily explained, though learned minds have elaborated ingenious theories, simple and complex, still we will maintain our text " The unity of Force " We will again note that electricity is but another name for the most exalted motion known We will then be able, in some degree, to comprehend its action upon our bodies, and its true place in medicine, and how it acts through the brain, and its infinite ramifications Nerve velocity is 60 yards per second, sound velocity is 332 yards per second, cannon ball velocity is 550 yards per second, light velocity is 360,000,000 yards per second, electrical velocity is 450,000,000 yards per second

Hence it can be readily understood, how electricity, direct action, may accelerate our natural forces, how its reverse action may depress them, how its chemical action may dissolve or electrolize morbid growth, how even may dilate the vascular system, or accelerate the vaso motor, and how, through the sympathetic system exalt the trophic powers, or produce inhibitory action

The attention of electricians was concentrated upon Electro Physics until the perfection of the mechanical contrivance by Morse In due time it was known to the medical profession that electricity was a powerful therapeutic agent, and its applications in the treatment of diseases wrested from the hands of quacks and charlatans Electro Therapy is now an important specialty in medicine The close analogy of electric to nerve force at once caused attention to be directed to its employment in the treatment of nervous diseases, but experiment has shown that it is applicable to the treatment, the relief and cure of other pathological conditions Thus it may be used as a tonic in cases of nervous debility, in cases of paralysis so as to take the place of nerve force which presides over functions of nutrition The nutrition of the paralysed limb is thus sustained, and likewise the revival of nervous energy promoted It is apparent from the close analogy of electricity to nerve force, that this agent embraces a wide range of therapeutic conditions Through the nervous cords which act as conductors, every part of the animal organism can be reached In this way secretion and elimination of morbid products may be promoted, and the organ or apparatus restored to healthy action

The three great forces of nature are heat, light and electricity These are the forces under whose influence vegetation is produced Heat and moisture cause the germ of life in seed to waken the materials stored up for the use of the embryo undergo changes both chemical and mechanical, so as to be fit for appropriation The architecture of the plant begins A spire shoots up from the bud, under the influence of the sun s light, the food afforded by the atmosphere is appropriated Forces are active at the root, and forces are active in the blade There is no doubt that electricity is one of the active forces which contributes to plant growth We have all the conditions of its generation, heat, moisture, unequal heating of different mineral substances, causing thermo electricity We also have chemical action It is impossible to draw a line of demarcation between vegetable and animal structure, and doubt not that heat, light and electricity are the physical forces under which animal structure is built up The light of the sun is as necessary to the vigor and health of the animal, as of the vegetable kingdom Indeed, as already stated, the two shade into each other so as to render it impossible to say where the vegetable ceases, and the animal begins Electricity being one of the forces which contributes to the animal organism, is necessary to functional health

The various conditions under which electricity is manifested enable us to apply it to a variety of morbid conditions Its wonderful decomposing power (electrolysis) has been utilized by the physician The intense heat incident to its manifestations by certain combinations, has enabled the surgeon to substitute in many cases the cautery for the knife, indeed to apply it to the section of morbid growths not remedial by the knife

It may be stated in order that progress shall be had in any branch of science, appropriate apparatus is necessary Scientific speculation is a great lever, but it must be controlled by experiment, speculation must be tested by experiment, for the human mind is too apt to be seduced by the pleasure of speculative philosophy, and too prone to abandon the paths of observation and sound induction From the want of apparatus and the ignorance of its different modes of manifestation, electricity as a therapeutic agent was seized upon by the charlatan and neglected by intelligent practitioners of medicine By a curious coincidence the discoveries of electric science and improved apparatus was accompanied by great discoveries in regard to the functions of the nervous system Whilst Oersted, Ampère, Faraday and others were making rapid strides in electric science, Sir Charles Bell, Magendie, *Marshall Hall, Claude* Bernard, Brown Sequard and others were unravelling the intricacies of the nervous system In no era of the world has there ever been such activity in scientific investigations, and the applications of science to the material comfort and welfare of mankind At last the votaries of medicine contribute their quota, and many of the most eminent of the profession are devoting their talents and energies to the therapeutical effects of electric force in the treatment of diseases

Electricity in suspended vital functions —We have been induced to try the effects of electricity in cases of suspended vital function resulting from narcosis, and cases of apparent death from drowning, from experiments upon living rabbits, made by Sir Wilson Phillips, of England, from which it appears that electric force was used to substitute nerve power The pneumogastric nerve of the animal was severed immediately after it had eaten some parsley After the death of the animal, which had great difficulty of breathing, and perished apparently from suffocation, the stomach was opened and the parsley found undigested A similar experiment of section of pneumogastric nerve was made, but a current of galvanism passed along the nerve, and continued for 26 hours of morbid products may be promoted, and the organ or apparatus restored to healthy action. The three great forces of nature are heat, light, and electricity. These are the forces under whose influence vegetation is produced. Heat and moisture cause the germ of life in seed to awaken, the materials stored up for the use of the embryo undergo change, both chemical and mechanical, so as to be fit for appropriation. The architecture of the plant begins. A spire shoots up from the bud, under the influence of the sun's light, the food afforded by the atmosphere is appropriated. Forces are active at the root, forces are active in the blade. There is no doubt, in my opinion, that electricity is one of the active forces which contribute to plant growth. We have all the conditions of its generation—heat, moisture, unequal heating of different mineral substances, causing thermo-electricity. We also have chemical action. It is impossible to draw a line of demarcation between vegetable and animal structure, and I doubt not that heat, light and electricity are the physical forces under which animal structure is built up. The light of the sun is as necessary to the health and vigor of the animal as of the vegetable kingdom. Indeed, as already stated, the two shade into each other so as to render it impossible to say where the vegetable ceases and the animal begins. Electricity, being one of the forces which contribute to the animal organism, is necessary to functional health.

ELECTRICAL FORCE IN MAN AND NATURE

All phenomena of the organic or inorganic world are now being interpreted in the terms of matter, motion and force. The pilot idea of the doctrine of evolution to day is that everything proceeds from the simple to the complex, and that back of all the manifestations of matter and of mind there lies "unity of force." It is this acting, living, persistent principle which constantly sits at the loom of time, and arranges the position and the texture of the threads that make up the web of things. This ancient weaver called "Force" has received many different names. When it works among molecules we call it cohesive attraction. When it works among the ultimate atoms, building them up into the delicate and beautiful crystals we call it the crystallizing forces. When engaged in uniting kindred atoms we call it chemical force, or chemical affinity. Our meaning, however, is sufficiently indicated without further extension of the list of forces.

Nature delights in prodigality of results, but she is parsimonious in the number of her working powers. Given a little matter and motion and she will construct a world. The lines of force radiate in all directions, always acting, always persistent. Difference of result is but the product of the same force differently conditioned. A tree and a mammal betray the same parent force. In the ultimate analysis we reach simplicity of cause and "unity of force."

Perhaps one of the most impressive instances of the play of force is to be seen in the phenomena of light. Light is but a result of the rapid oscillations of the ether waves. Hundreds of millions of these waves strike the retina before we are conscious of the sensation of light. How this sensation is translated into consciousness is a mode of force of which we know nothing. One fact, however, has been determined, viz., that color is a result of motion. Less rapid oscillations are required to produce in us the sensation of the red in the spectrum than o the violet. Electric light, which is the most intense of all light, is but a product of exalted motion. A certain degree of motion produces sound, this motion increased produces heat, a further increase produces all the colors of the spectrum in their regular order. Still exalting this motion, we obtain electric light.

The theory of wave motion in the ether had its origin in the wave motion of water and atmosphere. The ear sustains the same relation to sound that the eye does to light. There is a close analogy between the harmony of sound and the harmony of color. The rhythm of sound has its unvarying conditions in reference to the human ear. Atmospheric vibrations, when they exceed a certain number per second, lose their individuality, and become merged into a hum of indistinct sound. The auditory nerve is finely adapted to take in the whole range of the gamut. Sounds, higher or lower, in either direction, cease to be distinct.

It remains to say a word in reference to the more special manifestations of force. The human system supplies the most appropriate example. From the persistence of force we can but conclude that between the mind and body there is the closest relation, sensation, thought, and our most involved sentiments imply the destruction of waste of the gray tissue of the brain molecules. This waste is only another name for one mode of the "play of force." In a word, man, as he is, is but a product of force, acting, in the first instance, on a germ hardly microscopic, and mind, with all its wonderful and complicated powers, is evolved from the simplest beginnings. A Raphael or a Newton are evolved, in common with the lowest orders of animal life, from the product of the same force, controlled and governed by the same law, which had its fitting conditions and relations. Want of harmony in these, as we before remarked, implies want of harmony in result. A healthy mind, healthy morals and a healthy religion are the resultants of the unimpeded action of force.

THE ADVANCE OF MEDICAL SCIENCE

A knowledge of the brain and of the network of the nervous system is the essential to every educated physician, who would minister to a body, or to a mind diseased. The ability to maintain a proper medium, through the exaltation or depression of nerve power is requisite to him who would understand correctly the nervous system. Her path to universal empire, will continue to be, as it is now, dotted all along with rejected theories. She is now making rapid strides, and has indeed become an ocean of truth. Let us keep abreast, at least, of that portion of its mighty tide which is now carrying the science of medicine beyond its ancient land marks, enriching it with new truths. Just how electricity acts as a therapeutic agent, no experimenter has satisfactorily explained, though learned minds have elaborated ingenious theories, simple and complex, still we will maintain our text "The unity of Force." We will again note that electricity is but another name for the most exalted motion known. We will then be able, in some degree, to comprehend its action upon our bodies, and its true place in medicine, and how it acts through the brain, and its infinite ramifications. Nerve velocity is 60 yards per second, sound velocity is 332 yards per second, cannon ball velocity is 550 yards per second, light velocity is 360,000,000 yards per second, electrical velocity is 450,000,000 yards per second.

Hence it can be readily understood, how electricity, direct action, may accelerate our natural forces, how its reverse action may depress them, how its chemical action may dissolve or electrolize morbid growth, how even may dilate the vascular system, or accelerate the vaso motor, and how, through the sympathetic system exalt the trophic powers, or produce inhibitory action.

The attention of electricians was concentrated upon Electro Physics until the perfection of the mechanical contrivance by Morse. In due time it was known to the medical profession that electricity was a powerful therapeutic agent, and its applications in the treatment of diseases wrested from the hands of quacks and charlatans. Electro Therapy is now an important specialty in medicine. The close analogy of electric to nerve force at once caused attention to be directed to its employment in the treatment of nervous diseases, but experiment has shown that it is applicable to the treatment, the relief and cure of other pathological conditions. Thus it may be used as a tonic in cases of nervous debility, in cases of paralysis so as to take the place of nerve force which presides over functions of nutrition. The nutrition of the paralysed limb is thus sustained, and likewise the revival of nervous energy promoted. It is apparent from the close analogy of electricity to nerve force, that this agent embraces a wide range of therapeutic conditions. Through the nervous cords which act as conductors, every part of the animal organism can be reached. In this way secretion and elimination of morbid products may be promoted, and the organ or apparatus restored to healthy action.

The three great forces of nature are heat, light and electricity. These are the forces under whose influence vegetation is produced. Heat and moisture cause the germ of life in seed to waken, the materials stored up for the use of the embryo undergo changes both chemical and mechanical, so as to be fit for appropriation. The architecture of the plant begins. A spire shoots up from the bud, under the influence of the sun's light, the food afforded by the atmosphere is appropriated. Forces are active at the root, and forces are active in the blade. There is no doubt that electricity is one of the active forces which contributes to plant growth. We have all the conditions of its generation, heat, moisture, unequal heating of different mineral substances, causing thermo electricity. We also have chemical action. It is impossible to draw a line of demarcation between vegetable and animal structure, and doubt not that heat, light and electricity are the physical forces under which animal structure is built up. The light of the sun is as necessary to the vigor and health of the animal, as of the vegetable kingdom. Indeed, as already stated, the two shade into each other so as to render it impossible to say where the vegetable ceases, and the animal begins. Electricity being one of the forces which contributes to the animal organism, is necessary to functional health.

The various conditions under which electricity is manifested enable us to apply it to a variety of morbid conditions. Its wonderful decomposing power (electrolysis) has been utilized by the physician. The intense heat incident to its manifestations by certain combinations, has enabled the surgeon to substitute in many cases the cautery for the knife, indeed to apply it to the section of morbid growths not remedial by the knife.

It may be stated in order that progress shall be had in any branch of science, appropriate apparatus is necessary. Scientific speculation is a great lever, but it must be controlled by experiment, speculation must be tested by experiment, for the human mind is too apt to be seduced by the pleasure of speculative philosophy, and too prone to abandon the paths of observation and sound induction. From the want of apparatus and the ignorance of its different modes of manifestation, electricity as a therapeutic agent was seized upon by the charlatan and neglected by intelligent practitioners of medicine. By a curious coincidence the discoveries of electric science and improved apparatus was accompanied by great discoveries in regard to the functions of the nervous system. Whilst Oersted, Ampère, Faraday and others were making rapid strides in electric science, Sir Charles Bell, Magendie, Marshall Hall, Claude Bernard, Brown-Séquard and others were unravelling the intricacies of the nervous system. In no era of the world has there ever been such activity in scientific investigations, and the applications of science to the material comfort and welfare of mankind. At last the votaries of medicine contribute their quota, and many of the most eminent of the profession are devoting their talents and energies to the therapeutical effects of electric force in the treatment of diseases.

Electricity in suspended vital functions.—We have been induced to try the effects of electricity in cases of suspended vital function resulting from narcosis, and cases of apparent death from drowning, from experiments upon living rabbits, made by Sir Wilson Phillips, of England, from which it appears that electric force was used to substitute nerve power. The pneumogastric nerve of the animal was severed immediately after it had eaten some parsley. After the death of the animal, which had great difficulty of breathing, and perished apparently from suffocation, the stomach was opened and the parsley found undigested. A similar experiment of section of pneumogastric nerve was made, but a current of galvanism passed along the nerve, and continued for 26 hours

No difficulty of breathing occurred as long as the current was kept up The animal was killed, the stomach examined, the parsley was completely digested It thus appeared that galvanic energy is capable of supplying nervous influence in that the process of digestion may be carried on Similar experiments were made upon dogs with like results

Influence of Anæsthesia on Vaso-motor Forces of the Circulation—The following experiments by Drs Bowdich and Minot illustrate the influence of anæsthetics on vaso motor centres

Anæsthetics, in producing insensibility, have accomplished such results by antagonizing the effects of irritation of sensitive nerves One of the most constant physiological results of irritation of a sensitive nerve is a rise of arterial tension, due to a reflex stimulation through the vaso-motor centres of the muscular walls of the smaller arteries, especially those of the intestines It is ascertained that in the majority of cases, the rise of blood tension consequent upon the irritation of the saphenous nerves, is less marked when the animal is under the influence of ether, than when the anæsthetic is not used The first object was to determine the effects of anæsthesia on the reflex rise of the blood tension This was accomplished in the following manner An animal being placed on the operating table in the supine position, a solution of curari was injected into the jugalar vein, when paralysis ensued When the respiratory movement ceased, the trachea was connected by means of a glass canula inserted into it with the apparatus for artificial respiration, which was so adjusted as to imitate as closely as possible the normal respiratory rhythm A canula was then placed in the carotid artery and connected with a mercury manometer, carrying a pen by means of which the blood tension was recorded on a long strip of paper, which was kept in uniform motion by clock-work The saphenous nerve was then placed upon electrodes The irritation of the nerve was produced by closing the currents, by means of a key provided with a pen, thus recording the blood tension, which could be seen at a glance After the anæsthetic had been administered the nerve was again irritated Then the blood tension was notably decreased, and so continued to be as long as these experiments were tried

But far more constant and obvious were the results obtained from chloroform Here the irritation of the saphenous nerve caused a less marked rise in the blood tension, and sometimes there was no rise whatever These facts present to my mind the clearest evidence in favor of the electrical remedy in cases of deep chloroform toxæmia, and the propriety of having accessibility to a Faradic instrument, complete and ready for immediate use in chloroform administrations

E Du Bois-Reymond, "first succeeded in demonstrating the presence of specific muscle and nerve currents by deflection of the magnetic needle" He likewise ascertained that, "if the muscle or nerve be excited by electric currents, or by mechanical or chemical irritants, so that the first is physiologically active, and the latter caused to contract, and then placed at two symmetrical points in connection with the galvano multiplier, a less deflection of the needle is produced than when the nerve or muscle is in a quiescent state This is called the negative variation of the current" The conclusion arrived at by Du Bois Reymond was, that nerve and muscle contain innumerable positive and negative electric molecules which move with great regularity throughout the tissue Perchance the power of electricity in cases of suspended animation is to restore the suspended electrical forces of the body to a normal condition, and thus reanimate failing vitality

The effect of chloroform, the resuscitation of the still born, and of the tranced, and of the inert uterus in post partum hæmorrhage, may be remedied in much the same way, that is to say, by appealing to the vaso-motor centres through the pneumogastric axis

No nervous centre can act of its own motion or originate action It must be excited to action We might as well speak of sight without the action of the waves of the luminous ether, or sound without the vibration of sonorous substances In investigation medicine has called to her aid other physical sciences Natural philosophy has furnished the explanation of the mechanical contrivances, and we look to mechanics, hydraulics, and pneumatics to aid us to interpret the phenomena of locomotion, circulation, and respiration It has furnished in electricity the probable means of interpretation of the force which operates the mechanism, the phenomena of the nerve power, she has furnished the microscope to enable us to see things invisible to the naked sight, whilst chemistry has laid before us the knowledge of the fluids of the body, and enabled us to solve the mysteries of digestion These sciences have been called the hand maids of medicine, they are in fact parts of the whole, without them no physiology, without physiology no art of medicine

But with scalpel, microscope, and chemistry, we fail to delineate the anatomy of the nervous system It is a truth that, that which is is but the sequence of that which was The results of to day could not be had without the investigations of yesterday In like manner will the knowledge of to day be the basis of the conclusions of to-morrow—such is the law of intellectual development, such is the sequence of scientific advancement Sir Charles Bell first showed that the nerves of the human organization are distributed with regularity It is the basis of the physiology of the nervous system He first called attention to the functions of the spinal nerves, pointed out their different structures and their different functions, distinguished the sensory and the motor Marshall Hall succeeded Bell, and we had his excito motor system Others succeeded Hall to explain nervous phenomena, among whom stands preeminent the great Claude Bernard

But we owe more to Marshall Hall than the explanations he has given of nervous phenomena He demonstrated that when the scalpel and the microscope fail, to determine its anatomy, we can yet map out the anatomy of the system A physiological fact is as certain an indication of nervous distribution, as though we could follow its ramifications scalpel in hand or microscope to eye Observation and experiment is the thread which leads out of the labyrinth, without which we must be lost in its intricate mazes Marshall Hall has given us a map of the excito motor system of nerves, Bernard has shown their peripheral distribution The functions of the brain and spinal marrow are to be laid before us by pursuing the same line of investigation By experiment the number of devoted investigators give an earnest promise that the science of life may yet be illustrated, that the opprobrium that medicine is only the empiricism may be expunged, and that the day will yet arrive when medicine will be practised upon laws or principles known and recognized

The whole forms a beautiful piece of mechanism, whereby under the orders of certain nerve centres it is set in motion Blood flows in by the arteries regulated by the vaso motors, the veins receive it, and dilate under the direction of the vaso dilators, the muscular bands are brought into play by the nerve power conveyed to them, the result being what we call full nutrition When nerve power is exhausted or its exaltation diminishes, muscles relax, veins contract, the parts are freed from blood As a typical illustration of voluntary force we will cite its influence on the heart's action—say for seventy years—and, for convenience, fix the pulsations at sixty per minute Then we will have the proposition that $60 \times 60 = 3{,}600$ beats per hour Again, $3{,}600 \times 10 = 36{,}000$ beats in ten hours, or, in the words of the learned Draper, this little organ can execute "three thousand million beats without a stop, and propel a half million tons of blood, and momentarily wasting, repairs its own waste all this time"

The mathematical rhythm of four moving cavities, the perfect closure of its mitral and semi-lunar valves, and the regurgitating play of its tricuspid, have never failed Much more could be said of other vital organs, under the control of the involuntary force In the face of all these facts, how strikingly true is the saying, "How fearfully and wonderfully we are made," for, in regard to the heart, we have but to note that its nerve supply springs principally from three little ganglia, and a few nerve fibres originating from the brain, spinal and sympathetic How delicate the source, how fragile and thread like the conductors, how readily implicated, how sudden and certain the result Yet, in death from such a cause, how obscure the character of the lesion!

THE TREATMENT OF DISEASES BY THE HYPODERMATIC INJECTION OF OILS[1]

BY JOHN V SHOEMAKER, A M, M D,

OF PHILADELPHIA

Experimental and clinical observations have taught us that oils when they cannot be swallowed, or are rejected by the stomach, can be absorbed by inunction and subcutaneous injection, and numerous instances of the absorption and assimilation of oil and fat by the skin have been reported, and their value in certain conditions, employed in this way, has been fully recognised But the more rapid and effective use of these agents subcutaneously, while known, has had little or no practical application

Menzel[1] and Perco first demonstrated the subcutaneous absorption of fat by injecting an ounce of it in a fluid state, under the skin of a dog, and in the course of forty eight hours it disappeared, without leaving any local effect The first practical application of this discovery was probably made by Krueg on an insane patient who refused to eat Subcutaneous injections of olive oil, twice daily, were then administered, affording sufficient nourishment to keep the patient in good bodily vigor At the end of a month he was induced to take his food in the natural way, and the injections were discontinued

Shortly after this announcement of the practical effects in Krueg's case, a most important result from hypodermatic alimentation in a case of gastric ulcer was reported by Dr James T Whittaker, of Cincinnati, Ohio According to Dr Whittakers report,[3] after exhausting other medication the patient was given subcutaneous injections of drachm doses of milk, alternated with beef extract, every two hours for three days The temperature declined, the pulse became stronger, and the existing pains and delirium disappeared The milk and beef extract not being well borne by the skin, cod liver oil was substituted for them, two drachms being given every two hours for two days, and one day as much as eight ounces was introduced Two abscesses formed from the milk, but not any ill effects followed from the oil, which was not only well borne, but its introduction was also free from pain The inability of some of my patients to bear medicine taken into the stomach induced me, a few years ago, to test thoroughly the subcutaneous absorption of oil, and the effects which followed in some few of the cases under treatment

Case 1 —Constipation —Miss M, aged 43, was confined to her bed after an operation for cancer, bowels became sluggish, stomach irritable, and all efforts at evacuation failed for six days On the morning of the seventh day two drachms of castor oil was mixed with an equal quantity of oil of sweet almonds, in order to make the oil sufficiently fluid for use, with a large hypodermatic syringe the injection was deposited into the subcutaneous cellular tissue of the back An hour afterwards the patient complained of pains through the limbs, which continued to increase until a copious evacuation took place, an hour and a half elapsing from the giving of the injection to the evacuation, and another passage succeeding in a brief period

Case 2 —Obstinate Constipation,—I was called to see a young man, eighteen years of age, suffering with nausea and vomiting, bowels had not been moved for nine days Administered the ordinary remedies, which failed to act At the end of forty-eight hours gave two drachms of castor oil, diluted as before described, hypodermatically In the course of three hours a free movement from the bowels followed, and the patient was as well as usual in a few days

---

[3] Hypodermic Alimentation by Dr James T Whittaker M D Cincinnati Clinic Jan 22 1876

Case 3—*Scrofula*—R C, negro, aged 23, had a number of enlarged lymphatic glands around the neck, with several open ulcers Hypodermatic injections of two drachms of cod liver oil, twice daily, for four weeks, lessened the size of the enlarged glands, healed up the ulcers, and caused the patient to increase in weight The usual food by the mouth was allowed during the treatment

Case 4—*Syphilis*—Mrs G, aged 37, very anæmic, was brought to the Skin Hospital by her physician Tongue large, coated and flabby, complained greatly of dyspepsia and general debility Several tubercles and infiltrated patches of syphilis were well developed on the face Mercury and the potassium iodide had been administered at different times alone, with the effect of increasing the discomfort of the patient, and completely taking away all desire for food Cod liver oil was recommended subcutaneously, four drachms being given every day, in addition to the regular meals At the end of two weeks the improvement was marked and in seven days more the cod liver oil was discontinued, and the patient put upon small doses of the iodide of mercury, which rapidly completed the cure

Case 5—*Eczema*,—This patient was an anæmic man, aged 39, whose anus was covered with extensive patches of eczema, the infiltration being particularly severe on the flexor surfaces The itching was very obstinate, and little could be done to relieve it He had been thus afflicted for eleven years Pulse weak, appetite poor, digestion bad, with more or less constipation The patient was intelligent, and carefully described the different methods of treatment that he had undergone He was placed in the Skin Hospital, and two drachms of cod liver oil was administered subcutaneously three times daily, and an ordinary dressing was applied to the patches He rapidly showed signs of responding to the treatment Skin became lighter and more natural at the end of four weeks, and the eruption became less annoying and lighter in color During this period he was kept on good, substantial diet, and at the end of the fourth week tonics were given, and by the middle of the following month, just forty two days from the time of his admittance to the hospital, he was discharged cured

Case 6—*Paræsthesia, or Perverted Sensibility of the Skin*—R M, a man of 69 years of age, had been under treatment for four years at various dispensaries and hospitals for an unbearable itching sensation of the skin of the entire body, only obtaining, at short intervals, temporary relief When he came under my care the patient stated to me that worms were wriggling around in the skin, occasionally he thought they came out and ran over the surface, and almost set him wild with the horrible feeling that was caused by them "When they begin to bore, and then crawl around," he added, "I tear the skin violently" The surface of the integument revealed only abrasions resulting from the scratching and rubbing The disease was recognised as dependent upon a disordered state of the nervous system The usual and unusual remedies were all tried, but with no success When almost bordering on despair for a remedy, subcutaneous injection of two drachms of cod-liver oil was resorted to twice daily for a period of twelve days, when the patient pronounced himself much better In three weeks the unpleasant sensations vanished, and in about thirty days he was discharged cured

The cases referred to are but a few of the many that I have successfully treated by oil hypodermatically administered, alone or in conjunction with other suitable means The laxative action of castor oil, alluded to in the cases cited, has again and again been verified on many patients affected with constipation It might also be advisable, in cases of apoplexy, to test the effect of a more active purgative oil by placing it beneath the skin, in the form, for instance, of the cathartic principle of croton oil Not only has the rapid and good purgative result of oil used hypodermically been thus demonstrated, but its nutritive action, when thus applied, has been shown to be valuable in debility, dyspepsia, scrofula, tuberculosis, and in certain diseases of the skin and nervous systems It is the quickest and best method of introducing oil into the system It is an invaluable means of combating disease, particularly in the class of cases just enumerated, where more nutrition is required, and also for those patients who are either unable to swallow oil, or who cannot absorb and assimilate it by the alimentary canal Oil can be used subcutaneously, alone or combined with other suitable agents that can be easily dissolved in it It is a valuable menstruum for suspending in it other drugs for hypodermatic use It can be given in connection with a suitable diet, and even with other medication by the mouth, or it can be used alone for alimentation Oil deposited in this way in the tissues is absorbed, and is no doubt assimilated, and will alone keep up the nutrition of the body It will at times arrest or assist in relieving scrofula, and will benefit tuberculosis It is especially useful in diseases of the alimentary canal, as well as in all affections depending upon deficient nutrition It will very often overcome an impoverished state and give tone and vigor to the system

For a purgative action one or two injections of a drachm or two of castor oil usually suffices, but for a nutritive effect, the same quantity of one of the bland nourishing oils, *e g*, cod-liver or olive oil should be administered two or three times daily In the event that alimentation is depending solely upon the injections they should be given about every two hours

For the purpose of giving oil hypodermically, a large syringe provided with a needle of good calibre should be used, and the instrument should have a capacity of from two to eight drachms The injections can be made in almost any part of the body, well provided with subcutaneous cellular tissue, into which the oil should always be thoroughly deposited The points usually selected for the injections are the su perior and inferior scapular and sacral regions, on account of the subcutaneous cellular tissue being especially abundant there Injections can also be made in the arms, the chest, the back, the buttocks and the legs There is more or less irritation at the point of puncture of the skin, about the same as will be seen from the use of almost any hypodermatic injection Sometimes there will also be some attending smarting and burning followed always with redness and swelling, or the formation of a nodular elevation which usually disappears in from twelve to forty eight hours, No induration or inflammation follows the injections, provided the usual precautions are observed in using the hypodermic syringe properly, and the tissues of the person receiving it are in the normal condition Oil has been so injected by me in very many cases, occasionally as much as one-half ounce being used at a time, without setting up any inflammation of the skin, or producing any unfavorable effects

The results thus far realized show that by the hypodermatic injection of oils, certain conditions and diseases can be controlled, relieved or cured It is an invaluable method in which full dependence can be placed, especially when the alimentary canal can no longer absorb and assimilate food or medicine

A NEW COMBINED TROCAR AND CANULA AND ASPIRATING NEEDLE[1]

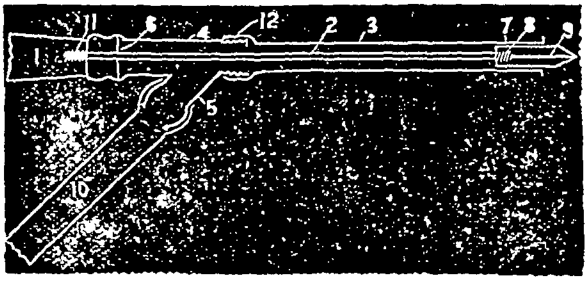
BY H LANDIS GETZ, M D,

OF MARSHALLTOWN IOWA

The common or simple trocar and canula has certain disadvantages, inconveniences or defects, as one may please to term its shortcomings One is the fact that we have no positive means of knowing just when the instrument is plunged properly, or to a sufficient depth, into the cavity, except by the amount of resistance encountered, unless the trocar is withdrawn from the canula, when, if we happen to have properly entered the cavity, no inconvenience will result If we have not, it may be necessary to re introduce the trocar and try again—a more or less bungling operation

Another objection is the fact that in the event of desiring to use a rubber tube, either as a matter of convenience or otherwise, we can only, or rather we are obliged to make the attachment to the canula after the trocar has been withdrawn This is quite inconvenient in some cases, especially would it be so if we desired to evacuate an abscess high up through the vagina Air would also be more likely to enter the cavity than by the use of the new device

The objections to the common *aspirating* or *exploring needle* are, either that we have no tube attachment, or that we require a regular aspirating outfit, which means more or less expense Another objection is the inability to remove the sharp or cutting portion of the needle after the cavity has been entered, consequently, as the cavity is being emptied, there is considerable danger of injuring or perforating the opposite surfaces, as in removing the effusion In case of pericarditis there would be danger of wounding the heart



The figure represents the trocar and canula, one half full size, with tube attached ready for use 1 Handle of wood, 2 Stylet, which screws into handle at 11 and at 8 into short trocar point, 3 Canula which screws on handle portion of canula at 12, 4 Handle portion of canula, 5 Part of handle portion of canula to which the rubber is attached, 6 Rubber disc making the canula air tight, 7 Perforation in canula for the admission of fluid, which indicates the entrance of trocar into the cavity, 8 Trocar point screws on stylet 9 Trocar point, 10 Rubber tube, 11 Stylet screws into handle, 12 Canula screws on handle portion of canula Parts 3 and 9 can be made of any size desired, and attached to 1, 2 and 4 The aspirating needle attaches to 1 at 11, and the canula for same attaches to 4 at 12

Seeing and realizing that these defects existed in the instruments in common use, I determined to overcome them as far as possible I now present (Fig) what I term a new combined "trocar and canula and aspirating needle," which, I believe, overcomes all the objections of the instruments now in use, and yet loses none of their advantages

PLACENTA PRÆVIA

BY H V SWERINGEN, A M, M D,

OF FORT WAYNE, IND

On Saturday morning, July 18th, 1885, Mrs C, a primapara, while engaged in shopping, was taken suddenly, without any premonitory warning, with a most profuse hæmorrhage, which, as the sequel will show, was uterine in character Her clothing was saturated with blood, and quite a pool of blood was discovered where she stood She was immediately placed in a carriage and driven to her residence, stopping on the way for her nurse to accompany her

I reached her bed soon after she was placed therein, and found she was yet flowing considerably Suspecting the nature of her situation, an examination revealed what is termed technically, *placenta prævia lateralis*

The presentation was the usual one, and the os uteri was dilated to about the size of a silver quarter dollar, dilatable, no pains I at once tamponed and administered ergot, which measures, while they checked at once the flow, did not absolutely control the oozing In the course of a few hours pains came on, when I removed the tampon, and, forming my fingers and thumb in the shape of a cone and introducing them into the os, had nothing else to do but to expand them to effect almost complete dilatation, so readily did the os yield Whether to turn and deliver at once or to rupture the membranes and allow the head to engage and proceed as in an ordinary labor, was now with me the question I chose the latter course As soon as the liquor amnii escaped the head engaged, and, by its pressure, stopped all hæmorrhage I now assured the patient that so far as *she* was concerned I considered her danger passed, and on account of the progress she was now making toward a speedy delivery, I had great hopes for the babe From this time on her labor progressed naturally enough, indeed more rapidly than is the case with the majority of primaparæ Probably an hour had not elapsed when the head rested upon the perineum The idea of employing the forceps never once suggested itself, because of the speedy progress of the case, and yet, when, in a short time after the head began to distend the perineum, the child was delivered, it was born dead, not the slightest evidence of life could be detected, it had undoubtedly been dead for some time During my first examination, however, its activity was a subject of remark The cord was around its neck, but this fact alone is insufficient to account for its death, there must have been pressure exerted upon it by the child's head soon after it became engaged in its route through the pelvis

---

[1] Read in the Section of Anatomy and Surgery at the Thirty Sixth Annual Meeting of the American Medical Association

Now, every case has its lesson to impart, as has every story its moral In the one before us, I am certain I could have saved the babe had I either turned and delivered, or applied the forceps the moment I broke the water, neither of which procedures, however, seemed nor were they necessary as aids to the mother in giving birth to the child A resort to either measure in this case would with great reason be considered "meddlesome midwifery" by those in attendance, and yet either one would undoubtedly have saved the life of the babe What is the obstetrician to do under these circumstances? Will some one answer? At this writing the mother is doing nicely, and would no doubt have done just as well had either the methods of delivery above suggested been adopted

Fort Wayne, Ind, Aug 10, 1885

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

The Pneumonia-Coccus of Friedlander —At the close of a valuable paper on this subject, Dr George M Sternberg draws the following conclusions

The pneumonia coccus of Friedlander is identical specifically with the micrococcus previously described by me, and which is commonly found in normal human saliva The capsule, or mucous envelope, which sometimes surrounds this micrococcus, described by Friedlander in 1883, and photographed by me two years previously, cannot be accepted as a distinguishing character of this species, inasmuch as it is not constantly present, and the circumstances upon which its development depends have not been accurately determined It is established that this is a pathogenic organism, as far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances It seems extremely probable that micrococci are concerned in the etiology of croupous pneumonia, and that the infectious nature of this disease is due to its presence in the fibrinous exudate into the pulmonary alveoli

But this cannot be considered as definitely established by the experiments which have thus far been made upon lower animals The constant presence of this micrococcus in the buccal secretions of healthy persons indicated that some other factor is required for the development of an attack of pneumonia, and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe This supposition enables us to account for the development of the numerous cases of pneumonia which cannot be traced to infection from without The germ being always present, auto infection is liable to occur when from alcoholism, sewer gas poisoning, crowd-poisoning, or any other depressing agency the vitality of the tissues is reduced below the resisting point We may suppose also that a reflex vaso motor paralysis, affecting a single lobe of the lung, for example, and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects

Again, we may suppose that a person, whose vital resisting power is reduced by any of the causes mentioned, may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in normal buccal secretions —*Am Jour Med Sc*, July, 1885

Amount of Pepsin in Gastric Juice in Normal and Pathological Conditions of the Stomach —Dr E Schutz, as the result of very careful examinations, draws the following conclusions The gastric juice, obtained by means of a tube from the healthy empty stomach, contains, as a rule, pepsin, the amount of which varies very little in the same individual at different times, but in different individuals it varies between 4 and 1 2 units Where the stomach is diseased, the pepsin obtained, under similar conditions as in the healthy person, is much less, as a rule, and may even be altogether absent in severe cases, or those that have lasted for some time In less severe cases there was also observed some diminution of the pepsin In nervous dyspepsia there is little or no change in the amount of this substance present also the same was noted in the dyspepsia of anæmic and chlorotic patients, and even in those suffering from tuberculosis A normal or only slightly decreased amount of pepsin is almost always accompanied by a strongly acid reaction of the gastric juice, whilst if the amount is much decreased, or there is none at all present, the reaction is, as a rule, alkaline, neutral, but feebly acid —*Deutsche medi-Zeitung*, May 4th, 1885 —*Bristol Med Chir Journal*, June, 1885

Power of Milk, taken from an Animal suffering from Splenic Fever, to Communicate the Disease to others —Messrs Chambrelent and Moussons, writing to the *Revue fur Thierheilkunde*, June, 1884, on this important matter, give the results of some experiments made by them

Feser of Munich, in the year of 1879, said that the milk of an animal suffering from splenic fever contained the infectious substance, and the following experiments of Messrs C and M confirm this statement

1 A Guinea-pig that had had a litter ten days previously was inoculated with the cultivated virus of anthrax, as a result of which it died in the course of a day An hour after its death, a drop of milk was removed from it, and cultivations were made in beef bouillon A guinea pig that was inoculated with a droop of this cultivation fluid died after two days, and in its blood the bacillus anthracis was found A second guinea-pig, which had been inoculated, died during the next day

2 A similar experiment, using the same methods but not the same animals, resulted in the death of two guinea pigs

3 With the same virus as used in experiment No 2, a rabbit, which was yielding milk at the time, was inoculated, but it remained healthy, and its milk did not produce anthrax bacilli on cultivation —*Deutsche mediz Zeit*, *No 56*—*Bristol Med Chir Journal*, June, 1885

MATERIA MEDICA AND THERAPEUTICS

Physiological Action of Cocaine —M Arloing has recently forwarded a long communication to the Biological Society on cocaine He has made a lengthy series of careful researches on the physiological action of cocaine, which lead him to draw the following conclusions The chlorhydrate of cocaine is a purely local anæsthetic Contact of the nerve-ending plate with cocaine is the principal cause of anæsthesia Cocaine provokes constriction of the capillary vessels, but M Arloing does not think that the corneal insensibility produced by cocaine ought to be attributed to regional anæmia, inasmuch as anæsthesia can be produced before and after the section of the cervical branch of the sympathetic The anæsthetic effects of cocaine salts are very evident on epithelial mucous membranes, on one especially in which the nerve terminations are intra epithelial—the corneal membrane, thus it may be argued that anæsthesia depends on contact, which is not affected by the local circulation In the more important nerves, where the nerve elements are protected by the perepheral connective tissue and the lamella sheaths, anæsthesia is produced more slowly, so slowly as sometimes to escape observation

Interstial injections of cocaine anæsthetize small nerves, as is proved by the enucleation of the eyeball A solution of cocaine deposited on the surface of the eye slowly penetrates through the epithelium, the nerve terminations are impregnated, traverses the cornea, circulates in the lymphatics of the eye and aqueous humour, bathes the iris and finally passes into the circulatory system and kills the guinea-pig M Arloing concludes, from his experiments, that salts temporarily modify the physical properties of protoplasma, the elements of nerve terminations, also fibullar elements M Brown Séquard believes that the anæsthetic effect of cocaine is due to inhibitory phenomena In a communication to the Biological Society he stated that the fact that wounds became anæsthetised when the animal's larynx is irritated by carbolic acid, chloroform, or galvanization, suggested to him that the action of cocaine is inhibitory By slightly irritating his own laryngeal mucous membrane he relieves a feeling of intense fatigue, and also removes rheumatic pain. He injected chlorhydrate of cocaine along the superior laryngeal nerve, all the wounds made the previous day were anæsthetised, the sciatic nerve was stretched without producing the slightest pain An analgesic zone exists around each wound, the wounds made after the application of cocaine were hyperalgesic M Brown-Séquard therefore refuses to admit the anæsthetic properties of cocaine, and further asserts that if a large dose is injected the poisonous properties of cocaine prevent the anæsthetic phenomena

A New Ether —M Rabuteau has prepared a new ether, the salicylate of methyl It is almost white, boils at 222° C, has an agreeable smell, and is almost insoluble in water It is prepared by treating methylic alcohol with salicylic acid or sulphuric acid, or even a better formula is that of sodium salicylate, sulphuric acid and alcohol It is not a saturated ether, it is a meno ethyl, and therefore almost an acid, and forms salts in presence of an alkali It colors salts of iron violet, and behaves like salicylate of soda in the presence of urine This ether does not produce thorough anæsthesia, and its effect is obtained by administering injections combined with inhalations Part of the dose of salicylate of methyl is utilized in the organism, and part eliminated by the respiratory and renal organs The vapor of salicylate of methyl exhaled is easily detected by being brought into contact with iron perchloride

MEDICINE

The Knee-Reflex in Diphtheria and its Sequelæ, and in Diabetes Mellitus —Bernhardt has for some years given considerable attention to this subject, as concerns diphtheria, and in a recent communication (*Archiv fur Pathologische Anatomie und Physiologie, und fur klinische Medicin*, March, 1885), he advances the following conclusions 1 In a very great number of patients who have suffered from diphtheria (of the throat and pharynx), the reflex disappears after the lapse of some weeks from the date of illness 2 This disappearance, although more common in severe cases which have been followed by paralytic affections, is not confined to them, but is found in mild cases which have no such sequelæ 3 The "Westphal's phenomenon" may not appear until two months from the date of the onset of the diphtheria, but it may have appeared and vanished within three weeks from the onset of the date of allow the head to engage and proceed as in an ordinary labor, was now with me the question I chose the latter course As soon as the liquor amnii escaped the head engaged, and, by its pressure, stopped all hæmorrhage I now assured the patient that so far as *she* was concerned I considered her danger passed, and on account of the progress she was now making toward a speedy delivery, I had great hopes for the babe From this time on her labor progressed naturally enough, indeed more rapidly than is the case with the majority of primaparæ Probably an hour had not elapsed when the head rested upon the perineum The idea of employing the forceps never once suggested itself, because of the speedy progress of the case, and yet, when, in a short time after the head began to distend the perineum, the child was delivered, it was born dead, not the slightest evidence of life could be detected, it had undoubtedly been dead for some time During my first examination, however, its activity was a subject of remark The cord was around its neck, but this fact alone is insufficient to account for its death, there must have been pressure exerted upon it by the child's head soon after it became engaged in its route through the pelvis

Now, every case has its lesson to impart, as has every story its moral In the one before us, I am certain I could have saved the babe had I either turned and delivered, or applied the forceps the moment I broke the water, neither of which procedures, however, seemed nor were they necessary as aids to the mother in giving birth to the child A resort to either measure in this case would with great reason be considered "meddlesome midwifery" by those in attendance, and yet either one would undoubtedly have saved the life of the babe What is the obstetrician to do under these circumstances? Will some one answer? At this writing the mother is doing nicely, and would no doubt have done just as well had either the methods of delivery above suggested been adopted

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

The Pneumonia-Coccus of Frildlandlr —At the close of a valuable paper on this subject, Dr George M Sternberg draws the following conclusions

The pneumonia-coccus of Friedlander is identical specifically with the micrococcus previously described by me, and which is commonly found in normal human saliva The capsule, or mucous envelope, which sometimes surrounds this micrococcus, described by Friedlander in 1883, and photographed by me two years previously, cannot be accepted as a distinguishing character of this species, inasmuch as it is not constantly present, and the circumstances upon which its development depends have not been accurately determined It is established that this is a pathogenic organism, as far as certain lower animals are concerned, and that its pathogenic power varies under different circumstances It seems extremely probable that micrococci are concerned in the etiology of croupous pneumonia, and that the infectious nature of this disease is due to its presence in the fibrinous exudate into the pulmonary alveoli

But this cannot be considered as definitely established by the experiments which have thus far been made upon lower animals The constant presence of this micrococcus in the buccal secretions of healthy persons indicated that some other factor is required for the development of an attack of pneumonia, and it seems probable that this other factor acts by reducing the vital resisting power of the pulmonary tissues, and thus making them vulnerable to the attacks of the microbe This supposition enables us to account for the development of the numerous cases of pneumonia which cannot be traced to infection from without The germ being always present, auto infection is liable to occur when from alcoholism, sewer gas poisoning, crowd-poisoning, or any other depressing agency the vitality of the tissues is reduced below the resisting point We may suppose also that a reflex vaso motor paralysis, affecting a single lobe of the lung, for example, and induced by exposure to cold, may so reduce the resisting power of the pulmonary tissue as to permit this micrococcus to produce its characteristic effects

Again, we may suppose that a person, whose vital resisting power is reduced by any of the causes mentioned, may be attacked by pneumonia from external infection with material containing a pathogenic variety of this micrococcus having a potency, permanent or acquired, greater than that possessed by the same organism in normal buccal secretions —*Am Jour Med Sc*, July, 1885

Amount of Pepsin in Gastric Juice in Normal and Pathological Conditions of the Stomach —Dr E Schutz, as the result of very careful examinations, draws the following conclusions The gastric juice, obtained by means of a tube from the healthy empty stomach, contains, as a rule, pepsin, the amount of which varies very little in the same individual at different times, but in different individuals it varies between 4 and 1 2 units Where the stomach is diseased, the pepsin obtained, under similar conditions as in the healthy person, is much less, as a rule, and may even be altogether absent in severe cases, or those that have lasted for some time *In* less severe cases there was also observed some diminution of the pepsin In nervous dyspepsia there is little or no change in the amount of this substance present also the same was noted in the dyspepsia of anæmic and chlorotic patients, and even in those suffering from tuberculosis A normal or only slightly decreased amount of pepsin is almost always accompanied by a strongly acid reaction of the gastric juice, whilst if the amount is much decreased, or there is none at *all* present, the reaction is, as a rule, alkaline, neutral, but feebly acid —*Deutsche mediz Zeitung*, May 4th, 1885 —*Bristol Med Chir Journal*, June, 1885

POWER OF MILK, TAKEN FROM AN ANIMAL SUFFERING FROM SPLENIC FEVER, TO COMMUNICATE THE DISEASE TO OTHERS —MESSRS CHAMBRELENT and MOUSSONS, writing to the *Revue fur Thierheilkunde*, June, 1884, on this important matter, give the results of some experiments made by them

Feser of Munich, in the year of 1879, said that the milk of an animal suffering from splenic fever contained the infectious substance, and the following experiments of Messrs C and M confirm this statement

1 A Guinea pig that had had a litter ten days previously was inoculated with the cultivated virus of anthrax, as a result of which it died in the course of a day An hour after its death, a drop of milk was removed from it, and cultivations were made in beef bouillon A guinea pig that was inoculated with a droop of this cultivation fluid died after two days, and in its blood the bacillus anthracis was found A second guinea-pig, which had been inoculated, died during the next day

2 A similar experiment, using the same methods but not the same animals, resulted in the death of two guinea-pigs

3 With the same virus as used in experiment No 2, a rabbit, which was yielding milk at the time, was inoculated, but it remained healthy, and its milk did not produce anthrax bacilli on cultivation —*Deutsche mediz Zeit*, *No 56* —*Bristol Med-Chir Journal*, June, 1885

MATERIA MEDICA AND THERAPEUTICS

PHYSIOLOGICAL ACTION OF COCAINE —M ARLOING has recently forwarded a long communication to the Biological Society on cocaine He has made a lengthy series of careful researches on the physiological action of cocaine, which lead him to draw the following conclusions The chlorhydrate of cocaine is a purely local anæsthetic Contact of the nerve-ending plate with cocainé is the principal cause of anæsthesia Cocaine provokes constriction of the capillary vessels, but M Arloing does not think that the corneal insensibility produced by cocaine ought to be attributed to regional anæmia, inasmuch as anæsthesia can be produced before and after the section of the cervical branch of the sympathetic The anæsthetic effects of cocaine salts are very evident on epithelial mucous membranes, on one especially in which the nerve terminations are intra-epithelial—the corneal membrane, thus it may be argued that anæsthesia depends on contact, which is not affected by the local circulation In the more important nerves, where the nerve elements are protected by the perepheral connective tissue and the lamella sheaths, anæsthesia is produced more slowly, so slowly as sometimes to escape observation

Interstial injections of cocaine anæsthetize small nerves, as is proved by the enucleation of the eyeball A solution of cocaine deposited on the surface of the eye slowly penetrates through the epithelium, the nerve terminations are impregnated, traverses the cornea, circulates in the lymphatics of the eye and aqueous humour, bathes the iris and finally passes into the circulatory system and kills the guinea-pig M Arloing concludes, from his experiments, that salts temporarily modify the physical properties of protoplasma, the elements of nerve terminations, also fibullar elements M Brown-Séquard believes that the anæsthetic effect of cocaine is due to inhibitory phenomena In a communication to the Biological Society he stated that the fact that wounds became anæsthetised when the animal's larynx is irritated by carbolic acid, chloroform, or galvanization, suggested to him that the action of cocaine is inhibitory By slightly irritating his own laryngeal mucous membrane he relieves a feeling of intense fatigue, and also removes rheumatic pain. He injected chlorhydrate of cocaine along the superior laryngeal nerve, all the wounds made the previous day were anæsthetised, the sciatic nerve was stretched without producing the slightest pain An analgesic zone exists around each wound, the wounds made after the application of cocaine were hyperalgesic M Brown-Séquard therefore refuses to admit the anæsthetic properties of cocaine, and further asserts that if a large dose is injected the poisonous properties of cocaine prevent the anæsthetic phenomena

A NEW ETHER —M RABUTEAU has prepared a new ether, the salicylate of methyl It is almost white, boils at 222° C, has an agreeable smell, and is almost insoluble in water It is prepared by treating methylic alcohol with salicylic acid or sulphuric acid, or even a better formula is that of sodium salicylate, sulphuric acid and alcohol It is not a saturated ether, it is a meno ethyl, and therefore almost an acid, and forms salts in presence of an alkali It colors salts of iron violet, and behaves like salicylate of soda in the presence of urine This ether does not produce thorough anæsthesia, and its effect is obtained by administering injections combined with inhalations Part of the dose of salicylate of methyl is utilized in the organism, and part eliminated by the respiratory and renal organs The vapor of salicylate of methyl exhaled is easily detected by being brought into contact with iron perchloride

MEDICINE

THE KNEE-REFLEX IN DIPHTHERIA AND ITS SEQUELÆ, AND IN DIABETES MELLITUS —BERNHARDT has for some years given considerable attention to this subject, as concerns diphtheria, and in a recent communication (*Archiv fur Pathologische Anatomie und Physiologie, und fur klinische Medicin*, March, 1885), he advances the following conclusions 1 In a very great number of patients who have suffered from diphtheria (of the throat and pharynx), the reflex disappears after the lapse of some weeks from the date of illness 2 This disappearance, although more common in severe cases which have been followed by paralytic affections, is not confined to them, but is found in mild cases which have no such sequelæ 3 The "Westphal's phenomenon" may not appear until two months from the date of the onset of the diphtheria, but it may have appeared and vanished within three weeks from the onset of the date of invasion 4 The reflexes frequently disappear on the one side before the other is affected, so that the knee phenomenon appears to be one-sided During the disappearance of the Westphal's phenomenon the return of the reflexes is also often at different times on the two sides 5 The reflexes may remain absent for a long time without any other sign of nervous change 6 These facts are of value in regard to testing the knee reflex in healthy persons, as after diphtheria a patient is not reckoned as healthy for five or six months 7 It has not been determined whether the knee reflex becomes altered at a later date than two months or if it remains healthy afterwards if unchanged within such a period 8 The skin and tendon reflexes do not show any parallelism in their presence or absence 9 Such investigations are only of value when the quadriceps is intact, no atrophy is present, and the muscular irritability has suffered no change

In diabetes mellitus, ROSENSTEIN (*Berlin Klin Wochensch*, No 8, 1885) comparing the particulars of cases observed with special reference to the knee phenomena, draws the following conclusions 1 In a number of diabetic cases the knee-reflex is permanently absent, and cannot be called back by subcutaneous injections of strychnine, as Schreiber has found to be the case in chronic alcoholism 2 The failure of this reflex stands in no relation to the amount of sugar in the urine, nor to the quantity of urinary contents giving the iron-chlorine reaction, nor to acetone, and cannot therefore be considered a toxic phenomenon 3 It is also independent of the general condition of the patients as to nourishment and bodily strength 4 So far as one post-mortem can be trusted, the disturbance of the reflex circuit, between the crural nerve and the lumbar cord, is functional and unconnected with organic alteration of the medulla Rosenstein does not incline to give much heed to this defect of patellar reflex, either in diagnosis or prognosis, but recognises in it merely another disturbance of innervation such as the paræsthesia, anæsthesia, neuralgia, and impotence, which are well known in diabetes —*Edinburgh Medical Journal*, July, 1885

INTRAVENOUS INJECTIONS OF LIQUOR AMMONIÆ IN CHOLERA —In the *Russkaia Meditzina*, No 8, 1885, p 157, DR JAKOV J TRUSEWICZ, of Cronstadt, recommends a trial of the intravenous injection of liquor ammoniæ (about three or four fluid pounds of water, containing from five to twenty drops of liquor ammoniæ to every six ounces) in the collapse and algide period of Asiatic cholera The transfusion of the ammoniated water in cholera would satisfy two indications, first, "it would augment the mass of the blood and neutralize an anomalous reaction of the latter," and, secondly, "being the best of all known analeptic means, liquor ammoniæ would stimulate the cardiac action " [*See* Dr Trusewicz's article in the *London Medical Record*, Feb, 1885, p 69 The author mentions three new instances illustrating the most powerful stimulating virtue of the hypodermic injection of five or seven drops of liquor ammoniæ in cases of apparently hopeless collapse In one of the cases, the injection revived a patient with enteric fever after musk and other usual stimulants had utterly failed In another case, in that of phthisis in the last stage, the author found the patient pulseless, deadly pale, cyanotic and delirious, in cold clammy perspiration, with stertorous breathing, reactionless pupils, and involuntary defæcation Two hypodermic injections, each of three drops of liquor ammoniæ, were made within twenty minutes, immediately after the second injection, the patient recovered consciousness, began to talk, and even joke, with his attendants, then fell asleep for five hours, and on the next morning heartily enjoyed his breakfast as if nothing had happened] The author also advises trial of the internal administration of liquor ammoniæ in in cholera cases In certain cases irritant baths of ammoniated water might prove of service Dr Trusewicz suggests, also, to give a trial to inhalations of oxygen as well as to systematic massage of the whole body, after Weir-Mitchell's plan —*London Medical Record*, July 15, 1885

COCAINE IN HAY FEVER —DR J WESTON BULL says that the eye does not seem to be protected against the irritating action of the pollen grain by two or three drops of a 2 per cent solution of hydrochlorate of cocaine, though the inflammation and itching, arising from the swelling and bursting of the grain, are allayed and removed by its use He is trying stronger solutions The violent sneezing and swelling of the mucous membrane of the nose, arising from the same cause, are removed by a few drops of a 1 per cent solution, sniffed off a camel's hair brush, so that, up to the present, he has been comparatively free from nasal symptoms

Probably the only way to ascertain the exact prophylactic effect, if any, of the cocaine, is to procure pollen which has a known irritating effect on the experimenter's conjunctiva, and to try its action on both eyes, having previously inserted solutions of varying strength into one of them, and these experiments he hopes to carry out

Apparently, as was anticipated, cocaine is at present our best topical application in the treatment of this distressing complaint, though Dr Bull found vaseline of great service last hay-season for the nose It certainly alleviates, and may be found prophylactic The only other effect on the eye is a slight smarting, soon wearing off, and a little dilatation of the pupil, lasting about twelve hours —*British Medical Journal*, July 4, 1885

THE PATHOLOGY OF HERPES ZOSTER —DUBLER, in *Virchow's Archiv* (vol xcvi, p 177), gives an account of two cases of herpes zoster in which he made a thorough anatomical and histological investigation In both he found distinct evidence of neuritis which extended to the cutaneous tings of the nerves, and he believes that the eruption is a true inflammatory one due to the extension of the inflammation from the nerve tings to the tissue of the skin He combats the view that the disease is a tropho neurosis depending on lesions in the ganglion of the posterior root, as he found these ganglia healthy in his cases

In one of his cases the inflammation of the nerves originated in a periostitis of three ribs, the corresponding intercostal series being affected. Another interesting point is that the neuritis extended somewhat into the muscular tings, just as other inflammations of nerves do, and in this connection it is very interesting that in several cases muscular paralysis has been associated with herpes, as in a case by Broadbent, where a herpes in the course of certain branches of the brachial plexus was associated with partial paralysis in the corresponding motor nerves, and one by Vernon in which with herpes zoster ophthalmicus, there was paralysis of the oculomotor nerve.—*Glasgow Medical Journal*, July, 1885.

SURGERY

ON RESECTION OF THE ANKLE.—In the *Bulletin de l'Academie Royale de Medecine de Belgique*, tome xviii, No. 12, DR. LIEBRECHT, of Liège, describes an operative procedure which he has recently devised for resection of the tibio tarsal articulation in cases of fungous arthritis. The methods that have hitherto been practised are all, he states, attended with much labor, in consequence of the difficulty in exposing and dividing the numerous ligaments of the ankle, and are apt to cause injury to the tendons, vessels, and nerves around the joint. The following is a description of the author's method, which, however, has up to the present time been performed only on the cadaver. The skin incision is made from the middle of the posterior border of one malleolus to the middle of that of the opposite malleolus. The tendo Achillis is then divided on a director. A second division, perpendicular to the first, is now made along the inner border of the tendo Achillis. This is about 2½ inches in length, and passing downwards, almost reaches the inner tuberosity of the calcaneum. The soft structures between the tendon and the bone are now dissected away, so as to expose the capsule of the joint and the posterior peroneo astragaloid ligament. On excision of these ligaments, the astragalus and the lower extremity of the tibia are exposed to view, and also the line of articulation between these bones, and below this, the astragalo-calcanean line. The tendon of the flexor longus pollicis is then displaced inwards from the posterior surface of the tibia, and all the tendons, vessels, and nerves situated behind the two malleoli can now be easily pushed forwards, so as to expose the whole of the posterior aspect of the joint. If the bones be hard, as is mostly the case in the cadaver, the posterior surface of the astragalus, at one of its borders near a malleolus, should be attacked with chisel and mallet. A notch should first me made along the whole width of the bone, so that by subsequent action of the chisel, the upper portion of the astragalus may be removed in one piece. If necessary, one or more slices of bone may be afterwards removed. The end of the tibia, if diseased, may be excised in a similar manner. If the diseased bone be very soft, it may be scooped away. The articular surfaces of the malleoli having been exposed, they may be scraped or removed with the chisel. The lateral ligaments may now be divided with a blunt-pointed bistoury. If any fragments of the astragalus remain adhering to the capsule or ligaments, they should be torn away with forceps. A large cavity is thus formed, at the bottom of which is found the articular capsule of the front of the foot, which may be readily scraped, or, if necessary, excised with scissors. If the loss of bone be not very great, and particularly if the malleoli have been partially preserved, the cavity may be left to become filled up by granulations, and then, after recovery, the patient will have a foot that is almost normal. When it has been found necessary to remove much bone, the opposed osseous surfaces of the leg and tarsus should be fixed together, so as to attain osseous ankylosis. Finally, the divided extremities of the tendo Achillis and edges of the external wound should be brought together by sutures.

Dr. Liebrecht claims for this operation the following advantages: "It does not cause any serious primary lesion, or necessitate any useless sacrifice, the soft parts and the periosteum are not bruised in the course of the operation. It offers more chances than the other methods of preserving a limb of normal form, and better assures the integrity of its functions. It may be easily and quickly performed. Owing to the position of the wound, the discharge of secretion will be effected without any difficulty, and the process of repair will be carried on much more rapidly."—*London Medical Record, July, 1885.*

ACUTE SUPPURATION AFTER FORCIBLE RUPTURE OF ARTICULAR ADHESIONS.—In the *Centralbl. fur Chirurgie*, No. 21, 1885, PROFESSOR M. OBERST reports four cases from the hospital practice of Volkmann, on which acute suppuration followed the breaking down of articular adhesions. In each of these cases, the ankylosis had followed an acute infective process. In two cases the primary affection was acute articular rheumatism, and in one the ankylosis was the result of acute infective osteomyelitis. In the fourth case, the nature of the primary affection could not be clearly made out, but there is no doubt, Oberst states, that it was some acute infective process. In two cases the suppuration caused by the breaking down of adhesions—in one in the cuticle, in the other in the knee—did not extend beyond the affected joint, whilst in the other two it was very extensive, and caused much disorganisation, necessitating amputation of the thigh in one of these instances, and causing death in the other. In the last case, which was one of ankylosis of the knee and deformity after acute rheumatism, forcible extension of the limb caused infraction of the inferior epiphysis of the femur, and was rapidly followed by acute and typical osteo-myelitis, with necrosis and formation of multiple abscesses in the medulla. Oberst thinks that the multiplicity of the abscesses, the character of the necrosis, and other morbid conditions in this case indicated that it was one of specific infective and not of simple septic osteo-myelitis, and it is suggested that it might have been due to the action of acute rheumatism. There can be no doubt, it is held, that in each of these four cases the suppuration set up by relatively slight force may be most readily explained by the supposition that, from the date of the primary acute affection during disease, germs had been left in the affected regions, and that, by the attempt to restore the functions of the joint, they had again been rendered mobile and placed under conditions favorable to the restoration of more active vitality In each case, the patient at the time of operation was quite healthy—except with regard to articular deformity—and free from fever, and in not a single instance did any abscess or fistula exist at this stage There could not, is stated, have been any infection from without, as the integument in each case was quite intact, and the extravasation of blood caused by the forcible movements of the joint did not reach the surface These cases, Oberst points out, should teach surgeons that they ought to be very cautious in attempting to break down ankyloses which have resulted from acute infective diseases In cases of this kind, a cutting operation would certainly be less dangerous than forcible rupture of the adhesions by simple manipulation In not one of the very numerous cutting operations that have been performed with orthopædic aims at the Oberst Hospital at Halle, has any instance been observed, Oberst states, of complication due to infection It is supposed that the micro organisms remaining after the primary disease find a much less favorable soil in the disinfected and antiseptically treated operation-wound, than in contused and lacerated tissues and in abundant or diffused extravasations of blood, conditions which often exist after forcible attempts to restore the functions of an ankylosed joint —*London Medical Record*, *July*, *1885*

Laparotomy for Ileus —Dr Edgar Kurz reports a case of laparotomy performed on account of intestinal obstruction The operation resulted in the complete recovery of the patient, and is interesting as being extremely rare in private practice

The patient, a man aged 33 years, twelve months previously had a severe attack of typhoid fever attended with numerous complications He recovered, however, and perfectly regained his health

In August, 1884, for the first time, he noticed a small hernia into the right inguinal canal which did not descend into the scrotum, and could easily be replaced within the abdominal canal October 23, 1884, Dr Kurz was summoned to the patient, and found him suffering severe abdominal pain, attended with vomiting Examination made at once, and the following day made it clear that the hernia was not the cause of the pain and vomiting Palpation of the abdomen was not painful, the urine was clear, and after an enema, which was followed by a movement of the bowels, the pain grew less severe However, the following night the pain returned, as also did the vomiting No results from enemata, no evidences of hernia, and the patient's countenance was the characteristic *facies abdominalis* Diagnosis was accordingly made of ileus As to its cause and location nothing could positively be stated The condition of the patient constantly became more serious, as evinced by stercoraceous vomiting, hiccough, and increased pain in the abdomen The temperature on October 29th and 30th, was 97 3° F, pulse 80 October 31st, the temperature became still lower, being only 96 4° F November 1st, the condition of the patient being in no wise improved, operation was decided upon After evacuating the bladder the abdomen was opened in the linea alba under a one and a half per cent carbolic spray While the incision was being made a severe attack of stercoraceous vomiting came on Examination revealed no signs of peritonitis Search was now made for cause of the obstruction, and a finger introduced into the ileo cæcal region discovered the presence of a ring in which the colon had become ensnared It was so tightly held that moderate traction was unable to release it, accordingly a probe-pointed bistoury was introduced and the ring twice incised The bowel was now readily withdrawn, and was found to be injected and intensely red The neck of the hernial sac was found to be a hand's breadth from the internal ring, which at once explained the negative result of all previous examinations After the replacement of the intestine the abdominal wound was closed by three silk peritoneal and six superficial sutures, which were rendered antiseptic by previous boiling in a 5 per cent, carbolic solution Iodoform was then applied and the wound covered with carbolized gauze, held in position by strips of adhesive plaster The operation lasted scarcely half an hour

The case progressed rapidly to recovery Movement of bowels took place for the first November 6th, and the 12th of November he was able to take short walks and drives At the present time he has resumed his ordinary employment, and is perfectly well Defecation is normal, and all traces of the hernia, previously existing, have disappeared —*Deutsche med Wochenschr*, March 26, 1885 —*Am Jour Med Sc*, July, 1885

Nephrectomy —At the close of an article on this subject, Professor S W Gross draws the following conclusions

1 That lumbar nephrectomy is a safer operation than abdominal nephrectomy

2 That primary extirpation of the kidney is indicated, first, in sarcoma of adult subjects, secondly, in benign neoplasms at any age, thirdly, in the early stage of tubercular disease, fourthly, in rupture of the ureter, and, lastly, in ureteral fistula

3 That nephrectomy should not be resorted to until after the failure of other measures, first, in subcutaneous laceration of the kidney, secondly, in protrusion of the kidney through a wound in the loin, thirdly, in recent wounds of the kidney or of the ureter, inflicted in the performance of ovariotomy, hysterectomy, or other operations, fourthly, in suppurative lesions, fifthly, in hydronephrosis and cysts, sixthly, in calculus of an otherwise healthy kidney, and, finally, in painful floating kidney

4 That nephrectomy is absolutely contraindicated, first, in sarcoma of children, secondly, in carcinoma at any age, unless, perhaps, the disease can be diagnosticated and removed at an early stage, and, thirdly, in the advanced period of tubercular disease —*Am Jour Med Sciences*, July, 1885

THE
Journal of the American Medical Association.
PUBLISHED WEEKLY.

THE EDITOR of this JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM IN ADVANCE	$5 00
SINGLE COPIES	10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address
JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, AUGUST 29, 1885.

THE INTERNATIONAL MEDICAL CONGRESS OF 1887 AND THE AMERICAN MEDICAL ASSOCIATION.

That mind must be curiously constituted which can complacently quote, as an index of public sentiment, the direct results of its own perversions and mis-statements of facts. And still this is what we find strikingly illustrated in the *Medical News* of the 22d inst. That journal makes quotations from the *Deutsche medicinische Wochenschrift*, *Le Progres Medicale* and the *Dublin Medical Press*. The spirit and substance of all these quotations may be briefly stated as follows: That the American Medical Association, at the meeting in New Orleans, set aside the Original Committee on the Organization of the Congress, together with all the work it had accomplished, appointed a New Committee of men selected without reference to their qualifications, and so restricted the American Membership that the Congress would "be a gathering of the American Medical Association, with a somewhat greater number of foreign guests than could otherwise be invited." These last three lines, together with many other sentences, are almost literally copied from editorials in the *News*, *Record*, and *New York Journal*. When our foreign brethren learn, as they will in due time, that they have been led by the editorials in these journals to base their disparaging comments on an entire perversion of the facts, their estimation of the character of some of those in whom they have hitherto placed much confidence will be materially altered. It is already well known, at least on this side of the Atlantic, that the American Medical Association, at New Orleans, neither displaced nor set aside a single member of the Original Committee of eight by whom the invitation was extended to the Congress in Copenhagen, neither did it, by any act or vote, nullify or set aside a single rule or regulation that had been adopted by the Committee for organization and government of the Congress, nor displace a single individual previously selected by the Committee as an officer of the Congress or of its Sections. On the contrary, the Association did set aside those members of the Committee who had been selected by the original eight chiefly from two or three cities, and put in their places a representative from the profession in each State and Territory, for the express purpose of having the Committee to make the preliminary arrangements for the Congress more fully represent the medical men of the whole United States. The Committee, thus enlarged and rendered more national in character and influence, was simply authorised to revise the work that had been previously done so far as it might deem proper. And nothing was more clearly indicated, both by speech and vote, than that the chief object of the proposed revision should be to make such changes *only as would give to the preliminary* organization a wider distribution of officers, and thereby make it more truly represent the 50,000 active, intelligent members of the profession of the United States, instead of having it limited largely to a select class in Philadelphia, New York and Washington, as had been proposed by the Original Committee.

There is not the shadow of truth in the statement so industriously circulated, especially *in Europe*, that the American Medical Association has in any conceivable way attempted to restrict the American Membership of the Congress to members of the Association, or had given any intimation to the Committee of Arrangements that such restriction was desirable. The truth is that the *Rule* for regulating the conditions of membership is still under advisement, and will not be definitely settled until the special meeting of the Committee called for September 3, 1885.

The question before the Committee is not whether the American Membership shall be restricted to members of the American Medical Association, for no such proposition has been made or entertained. But it is, whether it shall be representative, consisting of delegates appointed by the American Medical Association and its constituent State and local Societies, and by all the national organizations of special departments in medicine on the one hand, or on the other of all such members of the regular medical profession, either in this country or Europe, as may inscribe their names on the register and take out their tickets of admission. There is no reasonable doubt but that one of these propositions will be adopted at the coming meeting of the Committee. And certainly the adoption of either of them would secure a full attendance from the leading members of the profession from all parts of our country, and give to those who may come from the other side of the ocean as cordial a reception as they have had in any other part of the world.

COMPLETE DILATATION OF THE CERVIX UTERI, AN ESSENTIAL CONDITION TO THE TYPICAL FORCEPS OPERATION.

A few weeks ago, a zealous student of midwifery, and an original thinker of prominence, wrote the following sentence with reference to a rule of practice of vital importance in midwifery:

> "I regard the rule (not to apply the forceps till the os is completely dilated), long held by the ablest men, to be entirely erroneous, and capable of doing much harm to womankind and to the obstetric art. It is part and parcel, in my judgment, of those other rules, which have, by a singular want of knowledge of the great range of usefulness of the forceps, hampered mankind in its use.
>
> "I have no doubt that Chamberlen used the forceps as Lusk does, so far as his instrument allowed him, and two hundred years after him, in the face of thousands of facts to the contrary, we are still hampering the instrument with rules invented in the closet, and handed down from writer to writer, a heritage of ignorance, as I think, in lieu of a generalization from experience.
>
> "For myself, though my experience with the forceps is very limited, instead of regarding the dictum that they should not be used until the os is fully dilated, I take pride in stating that, so far as my recollection goes, in no case of my own was a woman ever allowed to lie in suffering and danger till the os was 'completely dilated.' When delivery was desirable, and the *os uteri* prepared for dilation, I proceeded to dilate it in a way as exactly after the manner of nature as I could conceive of, namely, by using the head itself as the dilator, and in so doing calling upon the uterus to aid my efforts."

We hope to be pardoned if we presume to suggest that a "limited experience" with the forceps disqualifies an operator for the expression of opinion upon the subject of the conditions of the forceps operation.

To avoid ambiguity in the use of terms, it may not be out of place to define our conception of the expression, "complete dilation of the *cervix uteri*." When the head descends into the cervical canal and pelvic cavity, the walls of the lower uterine segment become ultimately so far dilated that neck and vagina form one continuous canal, and the cervix is said to be completely dilated. When the head remains in the pelvic inlet, the external os may be completely dilated before rupture of the bag of membranes, but after the escape of the *liquor amnii* its walls may collapse, and present an aperture apparently passable by but three or four fingers. In reality, the os is completely dilated or dilatable.

We are very decidedly of the opinion that a serious study of the nature of the case, and a careful weighing of the opinions of those obstetricians whose views are entitled to distinguished consideration, will furnish evidence sufficient to establish the proposition that *complete dilatation of the cervix uteri is an essential condition to the typical forceps operation*. This postulate does not apply as a universal proposition to all forceps operations. There are cases—of seldom occurrence—in which, the application of the forceps is indicated when this condition is not present. To such operations, the term *atypical* has been well applied by Zweifel and others. The application of the forceps through an os not completely dilated is an operation at once difficult, dangerous and seldom indicated. The technical difficulties in the introduction of the instrument under the guidance of two or more fingers, as insisted upon by all modern authorities on operative obstetrics, are great.

Neglect of the precaution of the introduction of two or more fingers entails disastrous consequences. Hyernaux (*Presse Med.*, xviii, 10, 1865) records a case of perforation of the vaginal wall, with escape of intestines and omentum through the vulvar orifice between the thighs. The patient was a iv-para. Another case is reported (*M. f. G. B.*, 24, sup., pp. 157-208, 1865), in which the blade passed through the right vaginal wall, and perforated the bladder. The woman died from hæmorrhage, and the surgeon was sentenced to nineteen months imprisonment. The dangers of injury to mother and child are obvious. It is a very easy matter to grasp a portion of the cervical walls between the blade and the head. A case in point has recently come under our observation. The forceps was applied to the head, resting in the mid-plane of the pelvis, through an undilated os, by an able and experienced practitioner. Together with the head, a shred of tissue, six inches long by two broad, was extracted. Upon microscopical examination this shred of tissue proved to be a portion of the uterine walls. But the risk of producing cervical lacerations of all degrees, from a mere nicking of the edge of the external orifice to rents extending through the *corpus uteri*, involving the *parametrium* and pelvic peritoneum, is of more importance. It is scarcely necessary to call attention to the fact that the laceration, *per se*, is seldom of so grave prognostic moment as the danger of puerperal infection. The idea of using the head as a dilator is as old as the history of the forceps. The head is rarely a physiological dilator of the cervix That function is usually relegated to the bag of waters With the long, narrow-bladed forceps of Dr J E Taylor, there is great danger of injurious compression of the fœtal head, while with Simpson's, the volume is increased

The danger of injury to the fœtus is frequently not less than that to the mother It is well to bear in mind that sententious remark of Zweifel "The result of an operation is not always settled with the conclusion of the labor" Deafness and permanent injury of the *portio dura*—the results of injurious compression—come under our observation only too frequently According to the modern idea, the forceps is an instrument with which it is practically impossible to injure either mother or fœtus But the operation is seldom indicated The "personal equation of error" exercises great influence in the determination of the indications for the application of the forceps Under the direction of George Johnston, from 1869 to 1871, in the Rotunda Hospital, in Dublin, the number of forceps operation was 227 to 3,338 labors, or 1 14 7 In 1877, Lombe Atthill states that the number of forceps operations was 96 to 1,132 labors, or 1 11 8 It is not our purpose to investigate the motives of such operative procedures Class instruction, Dr Goodell's famous story of "reed-birds for supper," suggest themselves In Austria and Germany, the instrument is seldom applied more than once in fifty or sixty labors, and the results are far more favorable The increased mortality of the forceps operation in Dublin, and the United Kingdom generally, cannot be explained, however, simply on the ground of operative procedure when the necessary conditions and indications are not present, for the Viennese obstetricians are unusually skilful manipulators, and strict attention is paid to the prevention of puerperal fever

If special prominence be given to the doctrines of the Vienna school, in the attempt at summarizing the opinions of authorities on operative obstetrics, it is due to the fact that the colossal material, a system of records of critical accuracy, and liberal State encouragement have combined to give that famous school a peculiar vantage-ground We find an authoritative expression of opinion upon the subject in question in Dr Friedrich Schauta's "Grundriss der Operativen Geburtshilfe" "We demand, therefore, when the head is engaged in the pelvic inlet, the complete dilatation of the *os externum*, or, at least, its easy dilatability When the head is low down in the pelvic cavity, the forceps should never be applied until the greatest periphery of the head has passed the external uterine orifice" A similar rule of practice will be found in the text-books of Carl Braun, Josef Spaeth, and Gustav Braun This rule is rigidly enforced in the three obstetrical clinics of the Allgemeines Krankenhaus, with the favorable results, which have already been mentioned Dr Ludwig Kleinwachter (Grundriss der Geburtshulfe), states as an absolute condition for the application of the forceps, "The uterine os must be completely dilated" Otto Spiegelberg says "When the external orifice is not fully dilated, the forceps should only be applied when the head is small and the lower segment of the uterus dilatable, then only under the strictest indication" Such cases, he says, may occur in eclampsia with premature labor, but they always demand the highest technical skill (Lehrbuch der Geburtshulfe, 1882, p 743) In other words, complete dilatation of the os can be dispensed with only in *atypical* operations

Dr Paul Zweifel says, in his "Lehrbuch der Operativen Geburtshulfe" "The mouth of the uterus must be completely dilated" Pajot (Travaux d'Obstetrique et de Gynécologie) says that complete dilatation of the os is an indispensable condition to all forceps operations "Every application of the forceps," says Charpentier (Traite Pratique des Accouchements), "tried before the neck is dilated or dilatable, is an operation not only useless, but dangerous" Cazeux and Tarnier, "Obstetrics," say "The dilatation or the dilatability of the *os uteri* is even more indispensable here than in the case of version" Playfair says "For the safe and easy application of the instrument, it is also advisable that the os should be fully dilated, and the cervix retracted over the head" "If the os be not fully dilated, but is sufficiently open to admit of the passage of the forceps, the operation, under urgent circumstances, may be quite justifiable, but it must necessarily be a somewhat anxious one" Hodge says "The os uteri should be fully dilated, or, at least, very easily dilatable, before the instruments are applied"

On the other hand, Schrœder, Barnes and Lusk are disposed to dispense with this condition to a considerable degree Schrœder, however, demands that the *cervix uteri* shall have disappeared Barnes, while advocating the application of the forceps, when the head is at the inlet and the *liquor amnii* discharged, in lingering labors, even when the *cervix uteri* is not fully dilated, criticises the Dublin rules for operative procedure (Obst Transact, vol XXI, p 121) Lusk, while encouraging the practice of bringing the head into the cervix with the instrument, to act as a dilating wedge, says "I can only say that, with increased experience, my own practice has grown more and more conservative, and my own belief is that true wisdom requires us to abstain from even trivial operations so long as nature is able to do her work without our assistance" (The Science and Art of Midwifery, New York, 1883, p 343)

THE MONUMENT TO GENERAL GRANT

It is an unquestionable fact that the most fitting monument to a great or a good man, or to any one whose memory should be perpetuated by a material tangible structure, is something that will confer a material benefit to other people More than this, it is most probable that any man, whose memory is or will be of any value to his countrymen or to the world, would, if consulted on the subject, prefer that the money spent in erecting a memorial to him should be spent in such a way as to materially benefit a certain class or classes of people, and thus indirectly benefit all

The American people are now interested in building a suitable monument to General Grant The subject and enterprise are of national interest, and it is highly probable that a very large amount of money can be raised for the purpose The following, from our most esteemed lay contemporary *Puck*, is most apropos to this matter

"We have done enough, as a nation, and badly enough, in all conscience, in the monument line Let us to day, in a spirit of holy humility, try to resist the temptation to make further fools of ourselves We wish to perpetuate, in some material way, the memory of the great man who has just died So be it But let us not tie the remembrance of his greatness to another architectural or sculptural monstrosity Let us avoid the memorial style in which we have hitherto made ourselves ridiculous It is not likely that we shall ever build a good monument to General Grant, or that we shall even make a statue of him which will be artistically beautiful

"But there is no reason why we cannot found some institution, educational or charitable, that shall hand his name down to posterity in living strength and grandeur The monument that Peter Cooper raised for himself has done more to keep him in grateful remembrance of the people than moulded bronze or chiseled marble could ever do Let us not forget this when we cast about how fitly to do honor to our dead hero And while the public may be slow in responding to a call for money to build a useless and presumably ugly monument, they will not be apathetic when we ask for their help to raise a useful, noble, vital memorial to an honored name"

It may be suggested that a free educational institution would also serve the purpose of a charitable institution It is now quite certain that the State of Illinois, and the cities of New York and Chicago will spend quite large amounts of money in erecting monuments to the memory of General Grant And what monuments could be more fitting than those which would not only please the eye, but also be of lasting service to Humanity? People in America have shown that they are more willing to give money to a substantial good than to objects that are of immaterial benefit, and we think that should Illinois, as a State, and New York and Chicago determine to erect useful educational or charitable institutions in place of marble or bronze monuments, there would be but little difficulty in obtaining the necessary funds In a quite similar case no difficulty has been found in England in raising money for the Gordon Memorial Hospital (though this example is in no way meant as a suggestion) Furthermore, should the funds be appropriated to charitable or educational purposes the results would be capable of constant improvement—which otherwise would not be the case *Puck* has made, as usual, a very wise, common-sense suggestion

PUBLIC SENTIMENT OF THE PROFESSION

If those journals that have lent their pages to a free publication of all the perversions of the facts regarding the Committee of Arrangements for the International Congress, that the faction of obstructionists could invent, were as anxious to inform their readers of the true state of public sentiment as they are to quote the comments of foreign journals founded on their own misstatements, they would find place for the names of more than one hundred of the more prominent members of the profession in Philadelphia, and between three and four hundred more in other parts of that State, signed to a circular directly endorsing the action of the American Medical Association, and pledging their individual support to the International Congress, as an offset to the twenty-eight eminent Philadelphians who must have the honor of starting the disgraceful work of obstruction They would also be as quick to announce the fact that the Alleghany County Medical Society had at a full special meeting reconsidered its former vote, and unanimously endorsed the action of the American Association and its present Committee of Arrangements, as they were to herald its first hasty action

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, August 3d, 1885,

THE PRESIDENT, CHARLES T PARKES, M D,

IN THE CHAIR

DR FRANKLIN H MARTIN, read a paper on

OLEATE OF MANGANESE

He said There is little doubt left in the minds of therapeutists in regard to the value of manganese as a remedy in certain forms of menstrual trouble The remedy, in the form of permanganate of potash, was first brought to the attention of the profession by Ringer and Murrell, of London, in the spring of 1883 They recommended the drug in functional amenorrhœa Soon after this he commenced experiments with the same preparations, and published the results in the *Medical Record*, Sept 29, 1883 To his knowledge, that was the first that anything on the subject was published in this country

In the course of his experiments, acting on the theory that the drug produced menstruation by stimulating the menstrual organs, he was induced to give the remedy in menorrhagia and metrorrhagia dependent upon an *atonic* condition of the organ He found, to his gratification, that it acted equally well in these conditions as in the opposite He has also obtained good results from its administration in irregularities incident to approaching menopause He has received very gratifying letters from many members of the profession throughout the country, who have used the drug in one or more of the conditions mentioned above, with good results

Dr Thomas, of New York, says of the remedy "I think it is the best emmenagogue which has yet been discovered" Dr Roberts Bartholow not only recognizes its power as a remedial agent in amenorrhœa, but also considers it a general stimulant, making it equally efficacious in other menstrual difficulties dependent upon an *atonic* condition After publishing his second report on this subject, the author received a letter from Dr Sydney Ringer, of London, in which he expressed his gratification at the result of his experiments, and in which he said "Like you, I have found the permanganate most useful in atonic conditions," and further remarked, "I was quite prepared to learn that the permanganate is useful in menorrhagia"

Since there is no longer any doubt about the great value of this drug in the distressing menstrual difficulties, the next formidable problem for the therapeutist to solve is, How shall it be administered? The permanganate of potash, the original preparation used for experiments and administration, in any form is liable to act as an irritant to the stomach It has, in many ingenious ways, been made into pills, but as these pills must of necessity have for their basis kaolin, or some other inorganic substance, the drug in this form is not satisfactorily absorbed The compound tablets of Wyeth & Co, and other druggists, are objectionable in many cases of irritable stomach, because the irritating, undiluted drug comes in direct contact with its mucous membrane On account of the many difficulties of administration, therefore, this valuable remedy has not met with the reception that is its due Following the suggestion of Dr Lewis L McArthur, of this city, he succeeded in having an oleate of manganese prepared This oleate was made for him by Edward Kreyssler, of the firm of Forsyth & Schmid, of Chicago He says he is indebted to Mr Kreyssler for the following statement of the mode of preparation and of the physical and chemical properties of the oleate of manganese A solution of sulphate of manganese was made in distilled water, and to it a solution of sodium oleate was added On mixing these two solutions gradually, and with constant stirring, a precipitate of oleate of manganese resulted This precipitate, upon heating, changed to a putty-like mass This was washed several times with warm distilled water, to remove the sodium sulphate, and the resulting mass was the pure oleate of manganese It is of a light gray color, having a pinkish hue, of a sweet, musty taste, and peculiar, clay like odor It is sparingly soluble in alcohol, soluble in ether, chloroform, olive oil and oleic acid

The Method of Application—He recommends that one drachm of a twenty per cent solution of the oleate of manganese in oleic acid be applied to the abdomen of the patient, and its absorption promoted by friction with the hand In amenorrhœa it should be applied, if possible, every night for a week preceding the expected menstrual period, or at the time menstruation is due, and until it makes its appearance In menorrhagia or metrorrhagia it should be applied in smaller quantities every night, until the desired effect is produced Of about a dozen cases in which the oleate has been prescribed by him, but four had reported The success in these four was all that could be wished Three of the four were cases of *atonic amenorrhœa*, the fourth, irregularity due to approaching menopause

DR J H ETHERIDGE thought much advance would be made in the use of drugs if we were more careful to discover in what conditions they were beneficial He had found this remedy useful in cases of atonic amenorrhœa with the uterus in its normal position He had found the aqueous solution an eligible preparation, and had also used it in the form of a suppository

DR E J DOERING said he had used this remedy in some cases of atonic amenorrhœa with good results He asked the effect of the drug upon the pregnant uterus

DR PAOLI had used manganese somewhat for several years in cases of menstrual disorder, with varying degrees of success It was a useful remedy in many skin diseases He had not used the oleate, and could not see how it acted upon the uterus, unless, possibly, by being applied at once after being freshly prepared

DR MARTIN closed the discussion by saying he had used the aqueous solution in very small doses, also had had the remedy put in dry papers and swallowed with a glass of water He had never used it in the form of a suppository. Manganese has no effect on the pregnant uterus. The drug seems to act as a general stimulant to the uterus, causing it to perform its normal function. It might be absorbed as the oleate, and so produce its effects.

DR. JOHN BARTLETT read a paper on

LACERATION OF THE CERVIX UTERI,

in which he said his object in addressing the Society was to suggest a way and a time in which laceration of the cervix uteri may be easily and certainly detected soon after its occurrence. Directly after delivery, if the fingers be introduced deeply into the vagina up to the contracted os uteri internam, and then carried in any direction a little outwardly, the flabby and floating ring formed by the non-contracted cervix may be felt, as Guillemeau described it three hundred years ago, "like a section of large intestine."

By very carefully following the entire circumference of this ring an existing rent may be discovered. But this examination is attended with some difficulties. The patient is exhausted with her labor and fatigued with attentions, and just now, since "it is all over," longing for rest. She is impatient of, and perturbed by this *post factum* inquiry. Her state of mind and possible expression of complaint are apt to render an examination, which the physician cannot regard as absolutely necessary, less exact and thorough than it would be otherwise. And then, the soft and floating margins of the cervix have often somewhat of an intangible feel, if the expression be permitted, gliding past the fingers like a detached clot of blood, and occasionally, in some portion of their circumference, passing out of satisfactory reach. On this account it is not surprising to hear an obstetrician say that he cannot tell whether the post-partum cervix is lacerated or not. The error of the accoucheurs who fail to recognise such a condition is that they do not make their observation of the suspected cervix at the proper time. They examine the neck actually, as has just be done mentally—alter the clearance of the uterus. The favorable moment for the examination—and that, he said, was the special point of his remarks—is just as the placenta is beginning to occupy and distend the cervix. The collar of flesh is then not floating and uncertain in feel, but stretched and expanded, forming a distinct ring, easily followed in its entire circumference. At this moment, then, just as the cervical tube is being rendered tense by the placenta mass, any laceration in it may be detected with ease and certainty. Dr. Bartlett illustrated his remarks with earthenware models turned by a potter under his immediate direction.

DR. ETHERIDGE asked the author of the paper whether he had verified a case by speculum examination after discovering it in the way he had illustrated in his remarks.

DR. PARKES said he had great difficulty in detecting laceration after delivery, on account of the relaxed condition of the parts. He thought the suggestion of Dr. Bartlett as to the way to obviate this difficulty was a good one.

DR. DOERING inquired as to the size of lacerations he had found.

DR. BARTLETT concluded by saying that he had verified cases of laceration discovered in the manner proposed by him. The largest laceration he had found was one and a half inches in length, and the end of the little finger could be passed into it. In one case he encountered considerable hæmorrhage from such a rent, and this may be the cause of continuous loss of blood when the os is well contracted.

Stated Meeting, August 17, 1885.

THE PRESIDENT, C. T. PARKES, M. D., IN THE CHAIR.

The PRESIDENT reported

A CASE OF OVARIOTOMY.

In February, 1885, the patient, Mrs. R., aged 43, ten children, came under the care of Dr. O'Connell, of Ponca, Nebraska, who diagnosticated ovarian tumor. Dr. Parkes was requested to perform ovariotomy. He found the patient in fair condition generally, hopeful and clear-minded. The abdomen was glistening with distension. Fluctuation was extremely well marked in all directions and in all positions of the patient. No resonance anywhere. No umbilical hernia. Her trouble dated from August, 1884, when a small tumor was perceptible in the right side. It gradually increased in size until January 17, 1885, when local peritonitis set in and was followed by rapid distension. Ovariotomy was done March 24, 1885. The patient had been placed in a bright light and an incision four inches in length made in the abdominal walls, midway between the umbilicus and pubes, to the peritoneum. There was no peritoneal fluid, but fortunately the bright light enabled me to distinguish between the peritoneum and the sac of the tumor, so closely were they applied to each other by adhesions. The adhesions were broken down so far as the hand could reach. A trocar was next plunged into the tumor and about 18 quarts, or about 36 pounds, of a dark, sanguineous fluid evacuated. The sac was enormously distended and very thin. After the most of the contents were drawn off, the opening made by the trocar was closed by Nélaton's forceps. The sac was still adherent extensively laterally and posteriorly. These were destroyed as completely as possible, and yet it was impossible to draw the sac through the opening or to reach the deeper adhesions to the pelvis and flanks. Finally a free space was found in the right iliac fossa, the sac turned up and the pedicle found and secured. The greatest difficulty was found in separating the sac from the intestines, which were universally adherent to the posterior surface of the sac, and could only be reached by turning the tumor upwards after division of the pedicle. A firm, broad adhesion to the stomach at the top of the cyst could not be separated, so a portion of the outer wall of the cyst, corresponding in size to the adhesion, was dissected from the tumor, and in that manner the entire tumor was finally removed. The pedicle was about two inches long and very slender, and came from the right side of the uterus. It was noticed in the specimen exhibited that the sac was almost entire, and that it was not smooth and glistening, but rough from the adhesions, and at lower part there was an indurated mass about the size of a large orange The sac and mass together weighed but three pounds There was a vast area of oozing surface from which the adhesions had been torn, yet very little blood was lost The abdominal cavity was thoroughly sponged, a drainage tube introduced, and the wound closed by six silk ligatures

The length of the incision, after the removal of the tumor, was but two inches The patient progressed favorably until the fourth day, when she was attacked with severe and persistent vomiting, rising temperature and pulse Stercoraceous vomiting ensued and increasing exhaustion until her death, on the sixth day, pointed toward bowel obstruction

The points to be noticed in this case are the great extent of the adhesions, the only clear space being in the right iliac fossa, the only way to reach them being to ligate and separate the pedicle and then turn the sac upwards, the small size of the pedicle to such a large tumor It seemed to be approaching very near to the conditions of a free ovarian tumor explained by Mr Doran, who explains their presence by atrophy and abruption of the pedicle taking place when there are very vascular adhesions of the tumor to other parts, through which nourishment is carried on It was also noted that this patient went along all right for five days, them symptoms of intestinal obstruction set in The question was raised, whether it is not the urgent duty of the surgeon in such a case to reopen the abdominal wound and search for the seat of the obstruction and remove it

The PRESIDENT also reported

A CASE REQUIRING BATTEY'S OPERATION

Miss M , age 17, single, an American, had suffered greatly from pain referred to right iliac fossa, increased during menstrual periods, for one year previous to placing herself under his care, January, 1885 She was already an invalid Examination *per rectum et vaginam* disclosed retroversion of the uterus, accompanied with a dislocation of the right ovary into the Douglass *cul de sac* Medical treatment having failed, Battey's operation for the removal of the prolapsed ovary was done June 2, 1885 Nothing unusual occurred during the operation, and the patient convalesced rapidly The temperature never rose above 99° The dressing placed upon the wound was the dry dressing consisting of iodoform, antiseptic gauze and a layer of absorbent cotton This dressing was not removed until the seventh day, when the stitches were removed The line of cicatrix was perfect throughout There was no formation of pus The blood around the stitch holes was dry and scaly The case was remarkable, principally, for the absolute freedom from any discomfort during the recovery from the operation It was the first example of dry wounds Dr Parkes had ever seen The patient was out in three weeks The uterus was not fastened in its new position, and is slightly antiflexed, but not anteverted The morbid specimen exhibited is the ovary much enlarged with two small parovarian cysts developed on it

He then reported

A CASE OF DOUBLE OVARIOTOMY

Mrs P , æt 44, and had borne three children She complained of a tumor growing for the last two years over the situation of the gall bladder February 15, 1885, Dr Parkes made an exploratory operation, and after cutting into growth, out popped this biliary calculus, about one inch long and bean shaped Nothing further was done, and the tumor began to disappear However, during the manipulation of the abdominal walls he discovered two small tumors in the pelvis, in the region of the ovaries, which were supposed to be ovarian growths, but were not disturbed But they rapidly grew in size, and were removed by laparotomy on June 16, 1885 The bowels had been moved two days previously The abdominal incision disclosed the larger of the two tumors now shown, the larger filling the anterior inlet of the pelvis and held down by slight adhesions These were broken down and the mass removed It was found to be the degenerated right ovary The pedicle was extremely short and was with difficulty secured It was tied, divided, and the stump dropped Likewise the left ovary was removed and found to be degenerated The tumor being smaller and pedicle longer, no difficulty arose Finally, in sponging, quite free bleeding was noticed from the right pedicle It was again transfixed close to uterus and all hæmorrhage ceased

It was noticed that the sigmoid flexure of the colon was distended with fæces, and this condition was remarked as unaccountable, from the fact that free catharsis had been obtained only two days previously The patient did nicely for ten days after the operation, with the exception that no action of the bowels could be secured by medicines or enemata A careful digital examination revealed, high up in the rectum, a stricture which could not admit the end of the index finger The slight opening was surrounded on all sides by a thick, dense deposit of abnormal growth The question of relief seemed to stand between forcible dilatation of the stricture and the establishment of an artificial anus July 30, he dilated the stricture so as to admit three fingers in a cone shape The tissue was very dense It broke down with difficulty, and the induration extended up the bowel quite two inches After this was done the scybalous mass was easily removed By the next day the bowels had moved several times, freely, and tympany disappeared As Dr Parkes had to leave the city July 5th, the patient was left in the care of Dr R G Bogue, who subsequently told him the patient had died suddenly on July 10th, with symptoms of perforation of the bowels Two inquiries arise

1st Is it not well to examine the rectum thoroughly before operations, in all cases?

2d Would the establishment of an artificial opening, as soon as the nature of the obstruction was determined, have given a better result in the case reported?

Dr Parkes also exhibited a specimen of *epithelioma of vulva*, which he had removed by Paquelin's cautery

Dr Etheridge opened the discussion by asking how far we could go in removing portions of the intestine in cases of obstruction He said that he had recently had a trying experience in case of ovarian tumor, in which, after the operation, the patient reacted well, but in 48 hours vomiting came on, which soon became stercoraceous and the patient died On post-mortem examination, the whole of the large and most of the small intestines were greatly distended with flatus A short piece of the small intestine, just where it entered the large one, was collapsed, and with great difficulty could any of the flatus be forced through it He asked the author of the paper if he would have had the courage to have removed this portion of the intestine

Dr Franklin H Martin said he had been very much instructed and entertained by Dr Parkes' well detailed report It had impressed him with three points or lessons that were dwelt upon in a recent article by A Vander Veer, M D , of Albany, N Y , in the July number of the *American Journal of Obstetrics*, citing "personal observations on the work of Lawson Tait," at his private hospital in Birmingham, England These three points, which to his mind explain, to a great extent, the wonderful results of that great operator, are

1st Cleanliness, pure air and sunlight

2nd Efficient, good looking nurses

3rd Close personal supervision, and attention to after-treatment

In the first case that Dr Parkes reported to-night good light had saved him from going directly into the sac of the cyst in attempting to enter the peritoneum This case also, he suggested, might have fared better had he been present to have given personal attention to the movement of the bowels, thus, possibly, removing the obstruction which was apparently present In the third case, if personal attention had been given to the bowels sooner, the obstructions due to the stricture might have been removed and the ultimate result been more favorable Here the nurse was at fault Again, in the third case, if personal attention had been possible, the early operation of artificial anus, as Dr Parkes suggested, might have influenced favorably the ultimate result

Dr Weller thought that dilatation of the rectum was the only feasible method of relief in the case in which a malignant growth was formed in the lower bowel An operation for an artificial anus would have been difficult under the circumstances

Dr S H Stevenson asked why not open the sigmoid flexure and remove the accumulation from it at the time of the operation?

Dr Parkes closed the discussion by saying he would remove a portion of the intestine if it presented the only way of saving the patient's life If in a few days after the operation symptoms of obstruction should come on, he would reopen the wound and seek for the seat of the trouble He said that his theory of the best mode of procedure in these cases was gaining ground in the profession every day Dr Hamilton, of New York, lately reported a case of a gun shot wound of the abdomen, in which there were eleven perforations of the small and four of the large intestine These were sewed up and the patient recovered

The cause of the constriction in the case reported by Dr Etheridge was probably due to an obstruction of the arterial supply to this part of the intestine, causing it to contract Little good would come from an operation in this case He thought an artificial anus might have been made in the second case referred to in his paper, though the bowel was distended In these cases only a small opening was necessary This might have prolonged the patient's life a short time The cause of death was perforation of the bowels resulting from an ulcer incident to the dilatation of the rectum He generally used saline cathartics to open the bowels He would not have been justified in removing the accumulation from the sigmoid flexure at the time of operating, on account of the additional shock to the system it would have caused

Dr Henry T Byford then read some

OBSERVATIONS ON THE CAUSE AND TREATMENT OF INFANTILE ECZEMA AND ALLIED ERUPTIONS

He said, in the winter of 1880 he had been called to attend Mrs R in her fifth confinement Two of her other children were dead, and two more, apparently healthy at birth, had died in convulsions before they had completed one year of life Both of the last two had suffered from scabby eruptions and had become somewhat emaciated, but had not been considered syphilitic The child born at this time, seemingly healthy at first, soon broke out with what appeared to be an ordinary eczema pustulosum This eruption occurred on the scalp and on different parts of the body The child suffered from progressive emaciation, and at the age of three weeks it would easily have been mistaken for a case of struma, to be treated with cod liver oil The patient was quickly relieved by calomel in minute doses and mercurial inunctions

The next case referred to was that of Augustus G seen first in the summer of 1876 The child had pustular eczema of the scalp, great nocturnal restlessness, and suffered from progressive emaciation There was no cause to suspect syphilis from the appearance of the child, but the father acknowledged to what seemed to be a perfectly cured attack of syphilis The eczema rapidly disappeared, and the infant gained in flesh upon calomel powders and mercurial inunctions

In contrast with these syphilitic cases, he next mentioned the case of E H , a child one year of age, fat and well nourished, with no possibility of a syphilitic taint, but suffering from an eczema of the head, which spread over the body in patches Prolonged local treatment had not improved it The disease soon disappeared under the use of one-fifth grain powders of calomel, given twice a day, and an ointment composed of a dram of carbolic acid in an ounce of oxide of zinc ointment The child had been overfed and was put upon a restricted diet There was no return of the disease

The next case was one in which the eruption invaded the eyelids and caused great conjunctival sensitiveness. By the use of quarter grain doses of calomel, given twice a day until a laxative effect was produced, then once a day, combined with the external application of carbolized oxide of zinc ointment and a borax eye-water, the condition of the patient was soon greatly improved.

He had succeeded in relieving many other severe cases of eczema by the use of calomel, and it made no difference on what part of the body the eruption occurred, or what the condition of the patient was otherwise. That eczema so frequently occurs in infancy, the large size and great activity of the liver in early life, and the striking action of calomel, had led the author to associate indigestion with infantile eczema as cause and effect. In syphilitic cases the alterative powders often produced an amelioration in the skin trouble sooner than they could through their direct action upon the blood poison. In all cases it is important to regulate the diet. He knew of no authority who had considered derangements of the liver, and its accompanying disorders, as the chief cause of eruptions of the skin, or who had recommended calomel as the chief remedy for its cure. As calomel produced such prompt relief, and as improvement of digestion usually followed rather than attended the action of the remedy, one is led to believe that the cure is brought about not merely by improving digestion, but by a removal of waste irritating matter from the system, and from the great efficiency of mercury over other laxatives. He believed that the irritating materials are not only in the retained fæcal matter, but also in the blood—the products of imperfect digestion, assimilation and excretion. He was led to the use of calomel in eczema from noting its good effect in cases due to syphilis, and as these patients improved so well under its use, he next tried in cases where syphilis was only suspected, and then in all cases. The usual dose was from one quarter to one-eighth of a grain powder, given twice a day, the dose to be reduced if too great irritation of the bowels was produced. In cases of children over two and a half years of age, in order to avoid salivation, he usually gave purgative doses of calomel every six or eight days, and trusted to diet and other remedies in the meantime.

In the discussion **DR. E. J. DOERING** said he had not used calomel in eczema, but had had good results from the use of corrosive sublimate. He intended to use calomel after this in such cases, and he thought nothing better could be found to use in chronic cases.

DR. J. ZEISLER remarked that he was very much interested in this paper, and especially to hear that calomel was useful in eczematous skin diseases. He had always held the view advocated by Hebra, that eczema was caused by external causes, and required external applications for its cure. Calomel might be of use in cases due to syphilis. He would not use blue ointment on young children. He asked whether it would not be best to use some external application in cases where there were thick masses of crusts covering the diseased part, and also whether the author of the paper had found salicylic acid useful in this disease.

DR. C. W. PURDY thought retained excreta a cause of eczema, and called attention to the close relation existing between the intestinal tract and the skin, the condition of the one affecting the other. He had seen cases cured by the use of calomel, and would favor this treatment.

DR. J. A. ROBISON said that Dr. Byford had found mercury beneficial in syphilitic and non syphilitic cases probably because, given in small doses, it was a general tonic, as iron or cod liver oil, increasing the number of red blood corpuscles and enriching the blood. Thus it counteracted any dyscrasia present.

DR. BYFORD concluded by saying that Hebra was doubtless right in saying eczema is caused often by external causes, but in some cases it was clear to him that the disease is due to causes arising within the system itself. In later years Hebra had modified his ideas of this disease somewhat. Although eczema could be cured by external applications, when so treated it is very apt to return. It is not so when removed by the use of calomel. External medication would often hasten the cure. He did not use salicylic acid. He believed that calomel in these cases acted as an agent causing eliminations as well as being a tonic.

STATE MEDICINE

GOOD HEALTH RESULTS FROM SANITARY WORK

Sanitary authorities have claimed that the sanitary work which they have recommended to be done as a preparation for cholera,—such as preventing and abating nuisances, attending to drains, sewers, privies, and cesspools, cleaning up generally, and unusual carefulness in regard to foods and drinks,—would reduce the sickness and deaths from other diseases, even if cholera did not come. The weekly reports for July, 1885, to the Michigan State Board of Health, by physicians in different parts of the State, indicate that this claim is being realized in Michigan, so far as relates to the lessened sickness,—it having been lessened from nearly every disease, and greatly lessened from fevers and from diarrhœal and other diseases believed to be especially influenced by sanitary conditions and this is true notwithstanding the meteorological conditions in that month were rather more than usually unfavorable to health. It is proper to state, however, that the sickness in any month is influenced by the meteorological conditions in the preceding month, and that the meteorological conditions in June, 1885, were favorable to health.

Observations in Michigan for many years have shown that in July the meteorological conditions especially unfavorable to health are High temperature, excessive humidity of the atmosphere, and deficiency of ozone. The Bulletin of Health in Michigan July, 1885, says "For the month of July, 1885, compared with the average of corresponding months for the seven years 1879–1885, the temperature was slightly higher, the absolute and the relative humidity were more, and the day and the night ozone were less "

"Compared with the average for the months of July in the seven years, 1879–1885, remittent fever, intermittent fever dysentery, consumption of lungs, cholera infantum, diarrhœa, cholera morbus, measles, and whooping-cough, were less prevalent in July, 1885 "

A large part of this decrease in sickness has undoubtedly been due to the medical and sanitary journals and newspapers, which have constantly kept before the people the necessity for sanitary work and the facts as to the spread of cholera in Europe

It remains to be seen to what extent efforts for the exclusion of cholera from this country, and the general preparation for cholera by Boards of Health and the people, shall prove effectual, but even if cholera shall not be entirely prevented, there will remain the belief that the measures which have so greatly decreased the sickness from other diseases, cannot but have had their influence in decreasing it, and if cholera does not occur in this country it seems quite probable that, by reason of the suffering elsewhere, there may be as many cases of serious sickness prevented in this country as there have been cases of cholera in Europe But this may not continue without continued vigilance and effort

Health in Michigan in July, 1885, compared with the average in July for the seven years, 1879–85

Diseases arranged in order of greatest diminution of sickness in July 1885	Per cent of Reports stating Presence of Disease		Per cent of Reports more (*) or less (†) in July 1885 than the average for July 1879–85
	In July 1885	Average in July 1879–85	
Remittent fever	30	51	*21
Dysentery	15	32	*17
Intermittent fever	65	82	*17
Consumption of lungs	48	63	*15
Cholera infantum	20	33	*13
Diarrhœa	62	74	*12
Cholera Morbus	39	49	*10
Measles	8	17	* 9
Whooping cough	14	22	* 8
Pneumonia	10	16	* 6
Typho malarial fever	10	15	* 5
Diphtheria	11	16	* 5
Bronchitis	41	46	* 5
Rheumatism	59	64	* 5
Inflammat n of kidney	17	21	* 4
Scarlet fever	11	14	* 3
Typhoid fever	6	8	* 2
Membranous croup	1	2	* 1
Small pox	0	1	* 1
Inflammat n of bowels	16	17	* 1
Influenza	18	19	* 1
Erysipelas	21	22	* 1
Neuralgia	58	59	* 1
Puerperal fever	6	6	—
Inflammation of brain	6	6	—
Cerebro spinal menin s	8	5	† 3
Tonsilitis	36	32	† 4

It will be seen that there was less sickness than the average for July from nearly every disease reported From only two, cerebro spinal meningitis and tonsilitis, was there an increase

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Microbes of Mumps—Post-phenomena of Decapitation—Bust of Gueneau de Mussy—The Cholera in Spain—Dr Ferran

That mumps is a contagious as well as an infectious malady has long been known, but what the nature of the contagium was, was not so well understood Dr A Ollivier, Physician to the Children's Hospital in Paris, has made some researches with a view of ascertaining the correctness of the results previously obtained by Drs Capitan and Charrin, who had been occupied in the same line of research Like these two experimenters, Dr Ollivier discovered in the divers liquids of the economy, but principally in the blood and in the urine of patients suffering from mumps, micrococci of a special form, isolated, or united together in pairs or in the form of zooglœa, also batonnets or rods similar to what are found in the saliva, but less numerous These results were constantly obtained in patients suffering from mumps Analogous researches were made on children in health, and the results were absolutely negative, a fact which shows that there is something specific in the disease called mumps, and the presence of microbes in the saliva and other liquids, would constitute an important element in the diagnosis of this affection

The contagion or infection may be effected either by the air passages, or by the salivary glands In these two hypotheses, it will be understood that the period of incubation will vary according to the number of microbes in the organism, and the power of resistance of the subjects This theory would equally explain the appearance of sub-maxillary adenopathy which often follows mumps It at the same time explains the swelling of the testicles or of the ovaries which used to be attributed to metastasis, a term that is becoming obsolete, as it is now admitted that the phenomena co-existing or immediately following the principal malady are merely other manifestations of the same morbid condition which originally gave rise, as in this case, to the parotitis If these organs are affected, it is no doubt owing to the quantity of microbes, or to the intensity of their nocive influence The elimination of the microbes is effected by the urine, and may in this way give rise to albuminuria It may thus be seen that these phenomena would afford a rational explanation of the symptoms or of the various complications of the malady under consideration

As the development and propagation of mumps are attributed to the presence of these micro organisms, mumps must be looked upon as an infectious or contagious malady, and should therefore be classed with small pox, measles, scarlet fever, etc , and hence the absolute necessity for establishing isolation wards for patients so affected This interesting communication was made at a meeting of the Paris Academy of Medicine about a week ago, and it was made over to the Commission of Hygiene for examination, as Dr Ollivier was a candidate for the membership of the Academy in that Section

On July 2 a man by the name of Gagny was guillotined at Troyes for murder Fifteen minutes after the execution transfusion with blood drawn from a dog was practised through the carotid arteries in the detached head In exciting the hemispheres the following phenomena were observed contractions of the eyelids, movements of the lower jaw , effects that were noticed for the first time on the head of Gamahut, who was guillotined in May last Reflex movements were obtained by exciting by means of an electric current divers nerves of the face and of the hands, as well as movements of the heart twenty minutes after the execution The experimenters drew particular attention to one circumstance the heart was blocked up by clots of blood, a phenomenon never before observed in these cases The conclusion was that the circulation of the blood was probably arrested some seconds before the execution, and what gave rise to the supposition was that Gagny, on approaching the scaffold became quite livid in the face It is supposed that at that moment the circulation was completely arrested

A bust to the memory of Dr Noel Gueneau de Mussy is to be placed in the Hôtel Dieu A subscription is being raised for the purpose by Drs Fercol Fernet and Huchard, who were formerly pupils of the lamented deceased gentleman

According to reports just received in Paris, the cholera is committing great ravages in Spain, particularly at Valencia and Aranjuez The panic is such that the people are leaving in great numbers, and those that remain are so bewildered that they are unable to attend to their usual occupations Even the pharmacies are closed supplies are exhausted, and the peasants refuse to take in any more to the infected towns Commerce is arrested, and what adds to the distress of the agriculturists is the interdiction by the French government of the importation from Spain of fruits and vegetables grown on the surface of, or under the soil

It appears that the glory of Dr Ferran, of Valencia who has made himself famous by his inoculations against cholera, will soon be on the wane, as it has been discovered that the method introduced by him as a prophylaxy against the disease is of no value Moreover, he has brought himself in disrepute by refusing to communicate unreservedly his mode of procedure, and the nature of the liquid he is employing for these inoculations

The mission from France, composed of Prof Brouardel and two assistants, was rather cavalierly received by Dr Ferran, and the members have returned to Paris quite indignant Professor Brouardel has sent in his report to the Minister of Commerce, by whom he was delegated on this important mission, and he also read it at the Academy of Medicine on Tuesday last Space will not permit me to enter fully into the report, but I may mention that Dr Brouardel stigmatizes Dr Ferran's inoculations as a purely commercial speculation and his secrecy is regarded as unworthy of a member of the profession to which he belongs

Paris, July 10, 1885 A B

DOMESTIC CORRESPONDENCE

THE INTERNATIONAL MEDICAL CONGRESS

Dear Sir —In an editorial in your issue of Aug 15, it was stated, on what authority I do not know, that I had withdrawn my declination of the secretaryship of the International Medical Congress of 1877, and consented to assume that office The truth is that up to the present moment no official notice of such nomination has been sent me, nor has any publication of it been made, to my knowledge, except in the *Medical News*, for July 4 I do not, however wish to make any point of this, but beg that you will afford me space for a plain statement, as brief as I can make it of the facts in regard to this matter

On or about the 1st of June, the chairman of what is now known as the enlarged committee told me that Dr Billings would probably decline the office of Secretary General and asked me if, in that case I would accept the nomination I told him I would not seek any office, but that if it should appear to be for the promotion of harmony and of the success of the Congress, and the *nomination were offered me*, I would seriously consider whether I could undertake the work

After the enlarged committee had met in Chicago, a meeting of physicians was called here to receive a report of what had been done I was at this meeting for a *few minutes only*, and did not hear the report or know that it concerned me Subsequently I was told that my nomination as Secretary General had been announced and that the impression had been conveyed that I had been a party to ousting Dr Billings in my favor—in other words, that I had *intrigued to obtain a place not vacant* I have since *been told by the Secretary* of the committee that my nomination came from an *outside* source, and without any prompting on the part of those with whom I might have been supposed to be in league How any one who knew me should think me capable of action so completely at variance with my whole life, I could not and cannot understand Yet I found myself under this *imputation*, and felt compelled to subscribe my name to the protest of June 29, lest my not doing so should give color to the idea that I had so schemed

There was another reason, not of a personal character, for my joining in the protest The enlarged *committee* had adopted a rule which limited the conditions of membership, so far as Americans were concerned, while it left to foreigners free and untrammeled admission Of this I could not approve I at once wrote to the Secretary of the Committee, and declined the nomination as Secretary-General in advance of official notification, on the grounds, that I was *informed that* Dr Billings had not intended to resign, but had done so *only* because of the action of the enlarged committee, that the committee originally appointed had resigned, and that it was likely that the change of management would cause forfeiture of the foreign support of the Congress as well as of much of that expected from the profession in this country This letter I have not withdrawn

When I understood that there was hope of a compromise being effected in regard to the matters in dispute, and the propositions looking thereto were shown me, it seemed to me that they were faulty in that they dealt with the American membership only, and I ventured to submit one simply defining the conditions upon which any one, American or foreign, might come in In handing this to Dr Shoemaker, I gave him also a note of explanation, in which I said that if anything better was offered, I would gladly accept it So far as I know, this was the only expression of mine which could be construed into a withdrawal from my former position

My own conviction is, that it is contrary to all precedent for the American Medical Association to assume any control of the management of the Congress, which is a body by itself, and the members of which will be in no sense the guests of the Association, or subject to it Were I Secretary General of the Congress, I should not consider myself the appointee of the American Medical Association, nor responsible to it in any degree

And while it is eminently proper that the profession all over the country should be welcomed to membership in the Congress, and to a full share in its proceedings, the Association does not seem to me to be, in its present form, a sufficiently representative body to undertake to insure this, even if it could properly claim the right to do so

I trust that you will bear with me in what is perhaps the wearisome length of this statement of facts and opinions, but it has seemed to me to be due not only to myself, but to those who have been kind enough to consider me worthy of nomination to office in the Congress

No one can regret more than myself the prospect of wreck of a scheme in which the credit of the American profession is so deeply involved, and to avert it, I would gladly do all in my power, but cannot sacrifice my personal honor, or stifle my convictions I am, sir, Very respectfully yours,

JOHN H PACKARD,

1924 Spruce St , Philadelphia, Aug 19, 1885

[We received two communications from Philadelphia, each stating that Dr Packard had withdrawn his resignation accompanied by no explanations or conditions These were the authority on which we made the announcement in the JOURNAL We have since learned from our correspondent that Dr Packard's proposition to withdraw his resignation was based on certain conditions concerning the Rule relating to the admission of members of the Congress, as shown in the above letter But as those conditions were already under consideration by the Committee of Arrangements and sanctioned by a large proportion of the members, our correspondent regarded the conditions as substantially complied with We certainly had no desire to misrepresent the position of Dr Packard in any possible way Neither do we think that our correspondent had any such intention, and we cheerfully give space to Dr Packard's letter in full —EDITOR]

LACERATION OF THE PERINEUM

Dear Sir An article entitled "Laceration of Female Perineum," in a recent number of the JOURNAL, by H V Sweringer, A M , M D , induces me to state my views on the subject, inasmuch as he recommends that this accident be left to nature, or deferred to a more convenient season, which is, in my opinion, unsurgical His belief that that woman never lived who, at full term with her first child, did not have some laceration of the perineum or fourchette, is certainly very remarkable I certainly have seen many lacerations, for I have for many years made a practice of making ocular examination of every case of labor as soon as the placenta has been delivered, and I am quite as certain that I have very frequently seen the fourchette escape entire in primiparæ at full time, even after the use of the forceps Extensive laceration will sometimes occur, whether there is skilled attendance present or none, and he who recognises such an accident, and fails to repair it at once, or within twenty-four hours, is, in my opinion, very culpable

The objections urged by Dr Hamilton, and quoted by the author of the paper—"that the operation at best is liable to fail," I question, "and is made under many surgical disadvantages, and when the patient, both mentally and physically, is in the worst possible position to bear it," I admit, but what are anæsthetics for if not for just such moments, when a few inhalations of ether will render her unconscious of pain I cannot understand how the vulvar fissure is to regain its normal condition unless the surfaces, while raw, are coapted and retained in a surgical manner by sutures or pins It seems to me that no medical man of experience who examines women will deny that women who go with this accident untreated are deformed, and suffer a great variety of evils in consequence thereof, which it is unnecessary to specify

The argument urged, that immediate union is difficult to obtain on account of the discharges, does not hold good If a proper position be maintained, and the limbs moved synchronously, flexion and extension may be indulged in as frequently as the patient desires, so long as both limbs are moved together, and this may be ensured if the knees are kept bandaged together If necessary, the patient can be kept for a few days absolutely prone, which will entirely prevent lodgment of discharges in the wound, and, to a great extent, contact with it I have practised this in several cases with perfect success, where the women had the courage to obey instructions, and out of a large number of cases of immediate operation by sutures in my hands, there has not been a single failure to unite

The prone position I consider of great importance to obtain the desired result, and this is not so very hard to bear if bolsters and pillows are dispensed with Sutures of carbolized silk are more easily introduced, more comfortable to the patient, and answer the purpose in my hands as well as metallic sutures Lint, saturated with carbolized oil, prevents septic condition The bowels may be moved daily without injury to the parts I would urge upon physicians the importance and necessity of making ocular inspections in all cases— at least, where there is a suspicion of lesion and repair it at once A large curved needle and some very coarse *carbolized* silk can be carried in one's pocket book, without trouble, and will be ever ready

Very truly yours,
R B BONTECOU, M D
TROY, N Y , Aug 20, 1885

MEDICAL POLITICS AND THE INTERNATIONAL CONGRESS

Dear Sir The *New York Medical Record* appears to be the most prominent mouthpiece for the disaffected and eminent men who are specially known to European medicine It is not a little singular that the *Medical Press* and the *Lancet*, of England, should only know these few disaffected but eminent physicians The medical men of this country know that Dr A Flint Sr, Dr Flint, Jr, Dr L A Sayre and Dr Frank H Hamilton have done more for American medicine and surgery than the majority of the malcontents who appear to be better known to British journals than to the American profession

It may be possible that our friends on the other side of the water do not know that we have almost sixty millions of people and about ninety thousand medical men of all grades, or, in round numbers one physician to every six hundred inhabitants In fact, the supply is greater than the demand It may be fairly stated that we have thirty thousand charlatans, including homœopaths, eclectics, etc The American Medical Association has excluded the above-named named classes from membership in its body Self-respect, as well as the dignity of the American profession, should lead every medical man, both at home and abroad, to view with disfavor and contempt every effort, on the part of a few, to give these men a place in the International Medical Congress of 1887 These are the only men who dive into "medical politics," with the exception of a few specialists in New York, who have made a code to correspond to their professional dignity

Probably the profession abroad is not aware that we are almost destitute of laws regulating the practice of medicine, and that there are only three or four States in the Union in which physicians are required to pass an examining board in order to obtain a license to practise medicine and surgery There are over one hundred medical schools in this country, and four fifths of them grant a diploma for an attendance of two sessions of from four to six months It may be readily understood, from the above statement of facts, that the American Medical Association, in dealing with the question as to who shall attend the International Medical Congress in this country, has the legitimate right to exclude men who practise "isms," or those who claim the privilege of consulting with them, to the detriment of the profession, however eminent they may be Wherever scientific medicine is practised the name of Sir James Paget is known Is it to be supposed that he would feel honored in hobnobbing with a celebrated "herbalist," or with the eminent homœopath, Dr Argendank, whom the *Medical Record* wishes to advertise in its issue of July 18, 1885

Yours respectfully J F JENKINS, M D
Tecumseh, Mich , August 25, 1885

BOOK REVIEWS

HAY FEVER ITS ETIOLOGY AND TREATMENT By MORELL MACKENZIE M D, London Third Edition London J A Churchill, 1885 (Autograph copy)

Among the many interesting communications to the profession upon this subject, none are more concise and yet so comprehensive as this Each of Dr Mackenzie's works is a model of literary ability and *scientific research and this one is fully up to his* standard Preferring the simple term "hay fever" to the many "magnificent titles" suggested by others, the author at once presents the history and progress of study of the disease, citing as the first detailed account the cases mentioned by Bostwick, in 1819 The historical part of such a work is by no means the least instructive and in this the bibliography is complete while throughout the whole narrative one can easily see the patient elimination of conclusion and fact from early hypothesis and theory

As to the etiology, after analyzing the views of others Dr Mackenzie frankly states that the predisposing cause is the possession of a peculiar idiosyncrasy but upon what that idiosyncrasy depends is quite unknown He does not believe it mainly due to chronic disease of the nose, because so few of the many sufferers from chronic catarrh have hay fever, and because most of those who suffer from hay fever appear to be perfectly healthy as regards the nose except during the short period of acute attack The circumstances which influence this idiosyncrasy are considered in detail As to the race, it is the English and Americans who are almost the only sufferers from this complaint, in temperament nearly all belong to the active, energetic class of so-called nervous organization One of the most singular features of this complaint is that it is almost exclusively confined to persons of some education, and generally to those of fair social position Dwellers in town are much more prone to hay fever than those who live in the country, and many more men than women suffer from the disease

Dr Mackenzie gives emphasis to the powerful influence of heredity In twenty-seven of sixty one cases, one or more near relatives had suffered in the previous generation, and he several times had treated a father and child at the same time In keeping with this the writer had under his care last autumn father, mother and son from one family, all the victims of hay fever The exciting cause is, without doubt, our author says, pollen, the essential factor in the cases of those who possess the peculiar predisposition The proposition that hay fever depends upon gross structural changes *within* the nose is not endorsed "Though in some of the American cases morbid conditions, such as hypertrophy of portions of the turbinated bones, and chronic rhinitis, have been found, such cases will prove in the end, I believe, to be the exception rather than the rule I have treated hundreds of cases of chronic diseases of the nose who have never been affected with hay fever" Dr Mackenzie also refers to patients who, having been operated on by others in accord with this theory, were afterward found by him to have received no benefit This is not in harmony with our best American authorities, although their views are fully discussed The true cause, the author says, after quoting Blackley's experiments, is the action of the pollen on the mucous membrane How? By the passage of the pollen granules—which are only one-tenth the size of the blood corpuscle—into the blood vessels by actual penetration of the walls Hence the *malaise* which is experienced in hay fever may be due to the presence of this granular matter in the general circulation If Mackenzie is right in this, we may not expect positive cures from any operative interference in such cases, for though by the galvano cautery and snare the ability of the nasal mucous membrane to receive the impression necessary to produce hay fever, is limited, yet the conjunctiva and the mucous membrane of the whole respiratory tract remains, and we know that these become affected, not, probably, because the nose is affected, but yielding to the same influence, though, generally latter

While we may know how the pollen so quickly irritates the mucous membrane of some, we do not know why, and as no special condition of the seat of disease seems to explain it, we are forced to the conclusion that an idiosyncrasy exists, *i e*, some condition which renders the capillaries in the mucous membrane of some, more liable than others to the penetration of pollen granules, or, absorbtion having taken place, causes a peculiar excitation in those who are by the possession of this idiosyncrasy, rendered susceptible

Holding these views, attempted radical treatment may not result in success "If the poison be continually introduced—as it will be during the season—the antidote, if one exists, can have but little chance of effecting a cure" Dr Mackenzie's treatment of hay fever is founded upon his conclusions regarding the nature of the disease Avoidance of the cause, *by a sea voyage or living in the city* during the period when pollen is given off, protection by means of *cotton in the nostrils* and a gauze veil, care for the nervous system and increasing its resistance to exciting causes, these are the main indications, not neglecting the conjunctivitis, asthma and general febrile condition which may be present

Report of the Department of Health, City of Chicago, for the Years 1883 and 1884

Chicago Geo K Hazlitt 1885

Those interested in public health, especially that of large cities, will find some very interesting and instructive reading in this Report of Health Commissioner De Wolf In the very beginning of the report Dr De Wolf justly criticises the useless bit of "red-tape" which gives the cleansing of streets to the Department of Public Works, and the cleansing of alleys and removal of house garbage from streets and alleys to the Department of Health On this point he says "The cleaning of a great city—and keeping it clean—is a labor of enormous magnitude, and of the most vital importance, and as there is really no demarcation between filth of the street and filth in the alleys, there should be no division of responsibility in its removal, and, in my opinion, one contract should cover the whole Such a course *should* ensure efficiency and economy"

In addition to the usual duties of factory, dwelling-house, work shop, meat and stockyards inspection falling to the lot of the health department of a large and rapidly-growing city, the Health Department of Chicago has a permanent nuisance on hand, which must be looked to at all times—the Chicago river, or perhaps, more properly speaking, the south fork of the south branch of the river What to do with the river is the question now occupying the attention of a great many who know something about it, but many more who know nothing Though, of course, not included in this report, it is pertinent to speak here of a very recent (about August 15) analysis of the water of Chicago It has been claimed and asserted that the drinking water of the city is necessarily contaminated by sewage (entering the lake and being pumped back to the city from the "crib") The recent analysis by Professor John H Long shows that the drinking water of the city is free from sewage, and that, in comparison with the waters of some of the large Eastern cities it ranks among the best, if not the best on the list

The Report also includes a detailed statement of the Bureau of Tenement and Factory Inspection, by Chief Inspector Gehnung, a report of the Registrar of Vital Statistics, a mortality report of the city for 1883 and 1884, which is very complete, a very suggestive report from the Smoke Inspector, a report of work performed by the sanitary police, meat inspectors, day scavenger service, licensed night scavengers and dead animal contractors, and a report from the small pox hospital

A comparison of the mortality percentage of Chicago with that of other large cities will show that the efficient Health Commissioner, in spite of the many disadvantages of political red-tape and topography of the city, does not confine his good work to the making of an interesting and instructive report

Second Report of the State Board of Health of the State of Tennessee, October, 1880–December, 1884

Published by Authority Nashville Albert B Tavel, 1885

When we consider the difficult struggle that the physicians of Tennessee have had for many years in inducing the State legislature to make provisions for a State Board of Health and the very niggardly manner in which that Board has been provided for by the State since its establishment, we are somewhat surprised that there is anything left of it to make a report And one of the first facts that meet the eye of the reader of the report is that not a dollar has ever been provided for chemical work to be done for the Board, in fact, the Board would have been entirely without a chemist had it not been for the liberal offer of Professor Lupton, of Vanderbilt University, who offered five years ago to do the work without recompense

The volume opens with the report of the Secretary, Dr J Berrien Lindsley, which occupies over two hundred pages This is followed by a report on School Hygiene, by Dr Daniel F Wright, a paper of some seventy pages In connection with this might be read with profit the succeeding paper on Physical Training at the State Normal School Gymnasium, which is only too short, by Mary E W Jones, the Director Following these are report on Vital Statistics in Tennessee, by Dr J D Plunkett, the report of the Committee on Prisons in Tennessee, by Dr P D Sims, a report on Epidemics and Contagious Diseases, as they prevailed in the State in 1881–1882, by G B Thornton, a report by Dr Plunkett on Bovine Tuberculosis, one on Abattoirs by Dr Thornton, and two others by him on Gulf Coast Quarantine and the Conferences of State Boards of Health Dr James M Stafford contributes a paper on the Natural Divisions of Tennessee in their Relation to Disease, which with the succeeding paper on the Medical Topography of the Valley of East Tennessee, are valuable contributions to the Medical Geography of the State The remaining paper in the Report is by Dr Plunkett, on Ozone, and its Relations to Public Health The volume closes with the usual reports of local and county boards, etc

Although this volume is not such as should come from a Board of Health which is in good working order, it is certainly due to no fault of the Board or of the individual members of it that it is not The papers and reports show that the present Board is such as would make an efficient body for the protection of the health of the State should the people arouse their law makers to a sense of their duty to themselves and to their neighbors The papers are instructive, and are evidence that the writers only need State provision to do good work in public health

A Correlation Theory of Color-Perception By Charles A Oliver, A M, M D One of the Ophthalmic and Aural Surgeons to the St Mary's Hospital, Philadelphia, Pa A reprint from the American Journal of the Medical Sciences, January and April, 1885

The author has carefully and patiently studied the many conflicting and opposing theories of color-perception, and has done much toward their elucidation and simplification Accepting the theory of undulation, and that a difference in the number of vibrations makes a change in the natural result, he makes three positive assertions

First—That as these actions are perceived, there must be organs able to appreciate them,

Second—That each series of organs must have an apparatus able to respond to the quality of its perceived impressions,

Third—That as all natural imponderable stimuli are the resultants of a mere difference in the number of vibrations of one and the same ether, the organs for the receipt of the different varieties must be but analogues and modifications of each other

The author very properly advises the discontinuance of the terms "anthropochromatopsia," "hypo-anthropochromatopsia," "pseudochromatopsia," and the substitution of the much better English expressions, "normal human color-perceptions" and "subnormal human color-perceptions" The latter is subdivided into acquired and congenital

The article shows much study and originality, and its careful perusal will fully repay anyone who wishes clearer ideas of how natural colors are perceived

A Text-book of Physiology By M Foster, M A, M D, F R S, Prælector in Physiology and Fellow of Trinity College, Cambridge Third American from the Fourth and Revised English Edition With Extensive Notes and Additions, by Edward T Reichert, M D, Demonstrator of Experimental Physiology in the University of Pennsylvania With 271 Illustrations Philadelphia Lea Brothers & Co, 1885 Chicago Jansen, McClurg & Co

For several years Foster's Physiology has occupied a peculiar and quite enviable position among the text-books on this most important branch of medicine In the highest sense scientific, it should nevertheless be the constant companion of every student of medicine who has some other work on this subject as a text-book To the student who is not engaged in special physiological study it should be his most constant book of reference, while to him who is specially engaged in physiological work it is an absolute necessity

The present edition has not been greatly changed, indeed, there are but few essential changes, except in the general make-up of the book Quite a number of good illustrations have been added, and additions have been made to the appendix on the "Chemical Basis of the Human Body," by Mr Sheridan Lea, who has had charge of this department of the work in this as in former editions

ASSOCIATION ITEMS.

MEMBERSHIP BY APPLICATION

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, *upon application* endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership

Application for membership, accompanied with FIVE DOLLARS, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly JOURNAL OF THE ASSOCIATION will be forwarded for one year

RICHARD J DUNGLISON, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

AMERICAN RHINOLOGICAL ASSOCIATION —The third annual meeting of the American Rhinological Association will be held at Lexington, Ky , October 6th, 1885 Papers and discussion will be devoted exclusively to the diseases of the nasal passages and their sequences The officers for 1885 are President, P W Logan, M D , Knoxville, Tenn , First Vice-President, A DeVilbiss, M D , Toledo, Ohio, Second Vice-President, J A Stucky, M D , Lexington, Ky , Recording Secretary, C A Sims, M D , St Joseph, Mo , Librarian, N R Gordon, M D , Springfield, Ill Information concerning the full programme, membership, papers, attendance, etc , may be learned from any of the above officers of the association

REMOVING MICROBES FROM WATER —PROFESSOR FRANKLAND has, we read in the *Journal of the Society of Arts*, recently made a series of experiments on the relative efficiency of filtration, agitation with solid particles, and precipitation, as a means of removing micro organisms from water His method was to determine the number of organisms present in a given volume of the water, before and after filtration The filtering materials were greensand, silver sand, powdered glass, brickdust, coke, animal charcoal, and spongy iron These materials were all used in the same state of division, being made to pass through a sieve of forty meshes to the inch Columns six inches in height were used It was found that only greensand, coke, animal charcoal, and spongy iron wholly removed the micro organisms from the water filtered through them, and that this power was lost in every case, after the filters had been in operation a month With the exception of the animal charcoal, however, all these substances, even after being in operation for a month, continued to remove a very considerable proportion of the organisms present in the unfiltered water, and in this respect coke and spongy iron occupied the first place Water containing micro-organisms was also agitated with various substances in the same state of division as above mentioned, and after subsidence of the suspended particles, the number of organisms remaining was determined A gramme of substance was in general agitated with 50 cubic centimètres of water for a period of about 15 minutes It was found that a great reduction in the number of organisms could be produced in this way, and the complete removal of all organisms by agitation with coke is especially to be remarked Precipitation by "Clark's process" also showed that it affords a means of greatly reducing the number of these organisms in water Dr Frankland concludes from his experiments, that, although the production in large quantities of sterilized potable water is a matter of great difficulty, involving the continual renewal of filtering materials, yet there are numerous and simple methods of treatment which secure a large reduction in the number of organisms present in water —*British Med Journ* , Aug 15, 1885

THE WILBUR SCHOOL AND HOME FOR FEEBLE MINDED CHILDREN at Kalamazoo, Michigan, was opened for the admission of inmates on Monday, August 3, 1885 All who wish to enter the present school year should make application to DR C T WILBUR, Kalamazoo, Mich

SECRETARIES OF COUNTY MEDICAL SOCIETIES throughout the United States are particularly requested to send the names and addresses of the members of the Societies to the JOURNAL at their early convenience

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 15 1885 TO AUGUST 21 1885

Col John Campbell, Surgeon, granted leave of absence for one month

First Lieutenant Francis J Ives, Asst Surgeon (recently appointed), ordered for duty in Dep't Platte (S O 184, A G O , Aug 13, 1885)

Wolverton, W D , Major and Surgeon, granted leave of absence for twenty days (Washington Bks , D C) (S O 171, Dept of the East, Aug 14, 1885)

Maus, L M , Capt and Asst Surgeon, in addition to his other duties, assigned to duty as attending surgeon of the Department, Rifle Camp (S O 83, Dept of Dakota, Aug 3, 1885)

Black, C S , First Lieutenant and Asst Surgeon, upon return of troops F and L Third Cavalry to Fort Davis, Tex , to rejoin his proper station, Ft Clark, Tex (S O 98, Dept of Texas, Aug 13, 1885)

McCaw, W D , First Lieutenant and Asst Surgeon, having reported back at these hdqrs from detached service, ordered to rejoin his proper station, Fort Lyon, Col (S O 122, Dept of the Missouri, Aug 17, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING AUGUST 22 1885

Denman, M C , Surgeon, Simon, Wm J , Surgeon, to temporary duty at Annapolis, Me , as members of Board for physical examination of candidates for admission to U S Naval Academy

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED AUGUST 22 1885

Bailhache, P H , Surgeon, granted thirty days' leave of absence, August 15, 1885 Chairman of Board to examine candidates for appointment as cadet in the Revenue Marine Service, Aug 19, 1885

Irwin, Fairfax, Passed Assistant Surgeon Recorder of Board, Aug 19, 1885

Bailhache, P H , Surgeon, to proceed to Delaware Breakwater Quarantine as Inspector, Aug 15, 1885

Stoner, George W , Surgeon, granted leave of absence for thirty days, Aug 10, 1885

THE MINERAL FOODS AND HOW TO GIVE THEM[1]

BY R J NUNN, M D,
OF SAVANNAH GA

Huxley gives the following table of what a full grown man should weigh, and how this weight should be divided "Weight 154 pounds, made up thus Muscles and their appurtenances, 68 pounds, skeleton, 24 pounds, skin, 10½ pounds, fat, 28 pounds, brain, 3 pounds, thoracic viscera, 3¼ pounds, abdominal viscera, 11 pounds, blood which would drain from body, 7 pounds (*Med World*, Vol 3, p 8)" More or less rapidly these have all to be renewed, change is life, stagnation is death, to provide materials to rebuild the body, its bones, its muscles, its fat, its skin, its nerves, its viscera, etc, is one of the destinations of the food we consume, the other is to supply the force we require for existence, force to repair worn out tissues, force to think, force to labor, force to generate the heat necessary to the perfect working of the human machine,—for these purposes many and various elements are needed, and one or another constituent portion of the body may be starved by the absence from the food of the material necessary for its sustenance

Foods naturally divide themselves into two classes, the organic and the inorganic The organic foods are again divided into the plastic elements of nutrition (Liebig), the calorifient (Thomson), calorifacient (Pavy), the non nitrogenous or carbonaceous, and these have been subdivided into "1st, the hydrocarbons, fats, 2nd, the carbohydrates, starch, sugar, etc, and 3rd, principles such as alcohol and the vegetable acids, which do not strictly belong within either of the preceding groups" (Pavy)

The members of the organic group have been thoroughly discussed in all their bearings by numbers of eminent authorities, but the inorganic elements come in but for a very small share of attention We are told, it is true, that milk contains all the elements necessary to the building up of the body, although they are present in such proportions as to make it an unsuitable diet for an "adult population" (Chambers, p 23) Eggs, when the shells are included, furnish the necessary material to build up the body in all its parts, but our people do not eat the shells with their eggs Finally we are informed that "*if* we are supplied with nutritive salts through meat or other articles consumed, we can spare them without detriment from our bread" (Pavy) When the days of milk diet are past, and the era of candies and starches is entered upon, where the quantity of meat, and, indeed, most other nitrogenous foods, has been reduced to a minimum, and hot breads and cakes and various starchy pastes under fancy names are increased to the maximum, there is in fact, no source from which to draw a sufficient supply of the earthy foods Inorganic matter under the form of saline materials, and water are equally as essential for satisfying the requirements of life as the organic components of food Although such saline materials and water do not appear to be individually concerned in the interplay of changes which form the source of the phenomena of life, they nevertheless enter as essential elements into the constitution of the textures and fluids of the body, and thus must needs be supplied to an adequate extent to meet the requirements of nutrition and secretion with the food from without (Pavy)

The tone adopted by Dr Parkes when speaking of the mineral matters of the food seems to indicate that it is a path on which he treads with uncertain steps In the following quotations I have italicised some of those phrases which express the indecision of the writer as to the function and value of the mineral foods "The salts and water are as essential as the nitrogenous substances Lime, chiefly in the form of phosphate, is absent from no tissue, and *there is reason to think* ("Manual of Practical Hygiene," vol 1, p 207) no cell growth can go on without it, certainly in enlarging morbid growths and in rapidly-growing cells it is present in large amount Where phosphate of calcium was excluded from the diet the bones of an adult goat were not found by H Weiske to be poorer in lime, because *probably* lime was drawn from other parts, but the goat became weak and dull, so that nutrition was interfered with "

"Magnesia *is probably* also an essential constituent of growth in some tissues Potash and soda, in the forms of phosphates and chlorides, are equally important, and would seem to be especially concerned in the molecular currents Forming parts of almost all tissues, they are less fixed, so to speak, than the magnesian and lime salt It is also now certain that these two alkalies do not replace each other, and have a different distribution, and it is so far observable that the potash *seems* to be the alkali for the formed tissues, such as the blood cells or muscular fibre, while the soda salts are more largely contained in the intercellular fluids which bathe or encircle the tissues

---

[1] Read in the Section on Practical Medicine Materia Medica and Physiology at the Thirty Sixth Annual Meeting of the American Medical Association

The chlorine and phosphoric acids have also very peculiar properties, the former, *apparently* being easily set free, and then giving a very strong acid which has a special action on albuminates, and the latter having remarkable combining proportions with alkalies *Both are furnished in almost all foods*, the sodium chlorate also separately Iron is of course also essential for certain tissues or parts, especially for the red blood corpuscles and for the coloring matter in muscle, and, in small quantity is found almost in every tissue and in every food The sulphur and phosphorus of the tissues appear to enter specially as such with the albuminate "

"Some salts, especially those which form carbonates in the system, such as the lactates, tartrates, citrates, and acetates, give the alkalinity to the system which seems so necessary to the integrity of the molecular currents The state of malnutrition which in its highest degree we call scurvy, appears to follow inevitably on their absence " Compare this view with that of Pavy (p 17) ' These principles are hardly of sufficient importance in an alimentary point of view to call for their consideration under a distinct head "

Scurvy —In a description of the mode of living of the Icelanders given by Pavy (p 305), the inference is drawn that scurvy and leprosy, which are common on the island, result from an exclusively animal diet This conclusion seems to be rather strained, because no mention is made of the existence of similar diseases among the Esquimaux or the Greenlanders, or other nations who are likewise carnivorous, indeed, in another place (p 367), the author speaks of certain inhabitants of South America (Pampas Indians and Guachos) who are purely carnivorous, as being remarkable for their powers of endurance From this evidence it seems that we must look farther than the animal food for the cause of scurvy Has the absence of mineral food, and probably of albuminates also, anything to do with the production of scurvy? It is quite sure that certain of these are notably absent from the diet of the sailor, who is a well recognized subject for the disease The analysis by Girardin of brine shows that much of the nutritious matters, organic and mineral (phosphoric acid, lactic acid, magnesia) have passed out of the meat Liebig has reckoned the nutritive loss at one third, or even one half It appears from Kuhne's observations that myosin is soluble in a 10 per cent solution of chloride of sodium, and hence a large quantity of this substance necessarily passes into brine Analyses show, it is true, a large percentage of fibrin and cellular tissue in salt meat, but this is made up of indigestible nitrogenous substances which afford probably little real nutritive material" (Parkes, p 214) It does not require the eye of an expert to read here between the lines that the absence of mineral and nitrogenous foods would here be a powerful factor in production of scurvy

To be, if possible, a little more contradictory, Parkes (p 223) says "Men can be fed on meat for a long time, as a good deal of fat is then introduced, and if the meat be fresh (and raw) scurvy is not readily induced "

We will now examine the proportion of mineral matters to be found in various articles of food and in different dietaries

Composition of lean beef (Pavy)

Nitrogenous matter	19 3
Fat	3 6
Saline matter	5 1
Water	72 00
	100 0

A purely beef diet would require 3½ pounds to supply the amount of carbon necessary to sustain the human body in health (Chambers) This would be a waste of say 1½ pounds of meat, because the amount of nitrogen demanded by the system would be contained in about 2 pounds of beef, so that the remaining nitrogen would be useless It is not probable, however, that races of men living entirely upon meat, as, for example, the Pampas Indians would be much troubled with the scientific economy of their diet It is safe, then, to assume that the minimum of meat consumed under these circumstances would be 3½ pounds, which give 1,2,00 grains, say 3 ozs (av) of salts

Let us now turn to some of the dietaries, and see how they have been provided with inorganic foods

Subsistence diet (Pavy)

Nitrogenous matter	2 33
Fat	0 34
Carbohydrate	11 69
Mineral matter, none	

Diet of adult in full health with moderate exercise (Pavy) The dietaries of the English, French, Prussian and Austrian soldiers during peace are taken as the basis of this class The mean of these dietaries stands as follows

Nitrogenous matter	4 215
Fat	1 397
Carbohydrate	18 690
Mineral matter	0 714

About 357 grains of mineral matter, being less than one third the normal amount

Diet of active laborers (Pavy) To represent this class Dr Playfair has put together the dietaries of soldiers engaged in the arduous duties of warfare, English, French, Prussian, Austrian, Russian, Dutch, Federal and Confederate

The mean of the above gives the following quantities "

Nitrogenous matter	5 41
Fat	2 41
Carbohydrates	17 92
Mineral matter	0 08

The dietetic value of the food of the Royal Engineers is given as follows (Pavy)

Nitrogenous matter	5 08
Fat	2 91
Carbohydrates	22 22
Mineral matter	0 93

Diet of hard working laborers (Pavy)

Nitrogenous matter	5 64
Fat	2 34
Carbohydrates	20 41

The preceding is deduced from the dietary of the English navy in the Crimea, laborers working on the Rouen railway, weavers, tailors, blacksmiths, and English and French sailors

Diet of the English soldier on home service (Pavy)

	OUNCES
Nitrogenous matter	3 86
Fat	1 30
Carbohydrates	17 35
Mineral matter	0 808

This is according to Dr Parkes

Dr Playfair's analysis makes the organic matter higher and the mineral matter somewhat less

Nitrogenous matter	4 250
Fat	1 665
Carbohydrates	18 541
Mineral matter	0 789

Prison diet presents the extraordinary fact that more mineral matter is present in it than in those just mentioned, thus

	OUNCES
Hard labor diet, per diem	
Mineral matter	1 963
Light labor diet, per diem	
Mineral matter	1 715
Industrial employment diet, per diem	
Mineral matter	1 616
Penal diet, per diem	
Mineral matter	0 972
Punishment diet, per diem	
Mineral matter	0 368

In many of the analyses of diet no mention is made of the mineral matter, showing the low estimate placed upon its value as a nutritive element by the various writers upon the subject of dietetics Of course it must have been present, but perhaps in very minute quantity, and be it further remarked, that the analyses which are given do not suggest the condition in which the mineral matters exist in the diet, for it must not be forgotten that while showing well in chemical investigations, they may be in such a state as to be wholly indigestible

Wheat flour in some form constitutes the principal food of the persons with whom we have to deal, and if the higher grades of wheat are taken as examples, and if the whole grain could be digested and assimilated, its chemical composition would leave little to be desired, containing,

Nitrogenous matter	22 75
Starch	58 62
Dextrine, etc	9 50
Cellulose	3 50
Fatty matter	2 61
Mineral matter	3 02
	100 00

Unfortunately, however, most of the mineral matter is in a condition to pass undigested through the alimentary canal, even if employed as food, but in reality it is nearly all removed during the process of manufacture into flour, so that the proportion left is but 1 7 to 1 60, and this probably of undigestible matter Neither in the vegetable nor in the mineral kingdom can we find any digestible substance having the chemical composition or the mechanical construction of bone Strange indeed as it may appear, chemists seem to be somewhat divided as to the arrangement of its elements

"It was Scheele who announced that the earthy part of the bones is phosphate of lime A hundred parts of fresh bone are reduced to about sixty by calcination"

"According to the analysis of M Berzelius, human bones deprived of water and fat have the following composition Animal matter reducible to gelatine by decoction, 32 17, insoluble animal substance, 1 13, phosphate of lime, 51 4, carbonate of lime, 11 30, fluate of lime, 2 0, phosphate of magnesia, 1 16, soda and muriate of soda, 1 20

"Fourcroy and M Vauquelin, in their first trials, did not find phosphate of magnesia in human bones According to M Hildebrandt, there is none of that substance in them According to Dr Hatchett, there is sulphate of lime in them, which, according to M Berzelius, is a product of calcination Lastly, Fourcroy and Vauquelin admit moreover in the bones, iron, magnesia, silica, alumina, and phosphate of ammonia, but no fluate" (Beclard's Anatomy, pp 259, 260

"The bones of different animals differ somewhat in composition With reference to the bones of *mammalia* the following has been established Those of herbivora are somewhat richer in carbonate of lime than those of carnivora, those of pachydomata and cetacea are particularly rich in it" (Lehman's Chemical Physiology, p 205)

The analysis by Marchand gives

Organic matter	
Cartilage insoluble in hydrochloric acid	27 23
Cartilage soluble in hydrochloric acid	5 02
Vessels	1 01
Inorganic matter	
Phosphate of lime	52 26
Fluoride of calcium	1 00
Carbonate of lime	10 21
Phosphate of magnesia	1 05
Soda	92
Chloride of sodium	0 25
Oxides of iron and manganese and loss	1 05
	100 00

Von Bibra's figures are as follows

Organic matter	
Cartilage	29 54
Fat	1 82
Inorganic matter	
Phosphate of lime with a little fluoride of calcium	57 42
Carbonate of lime	8 92
Phosphate of magnesia	1 70
Soluble salts	0 60
	100 00

"According to Dr Stark, the relative proportions of cartilaginous and earthy matter in the bone of different animals, in the bones of the same animal at different ages, and in the different bones of the same body, never depart widely from the preceding standard, the amount of earthy matter being always found to be just double that of the cartilaginous basis when the bones have been carefully freed from oily matter and completely dried previous to analysis The hardness of the bone, he maintains, does not at all depend upon an unusually large proportion of earthy matter, nor does their increased flexibility and tran parency indicate a deficiency of the mineral ingredients, for the transparent, readily cut bones of fish contain the same amount of earthy matter in proportion to their gelatinous basis as do the dense, ivory-like bones of the deer or sheep. The same holds good of the bones even of the so called cartilaginous fish. The difference appears to depend upon the molecular arrangement of the ultimate particles, and especially, it seems likely, upon the relative amount of water which the bones contain." (Carpenter's Physiology, p. 271.)

To be of any real advantage, the minerals must become a portion of the food of the people. It is not to be expected that each will take a dose of syrup or elixir, or a powder or a pill at each meal. It will not be done. The mineral food must be in the bread, in the cakes, in the soup, it must be everywhere in sufficient quantity to effect its mission, but without permitting its presence to be detected by any change of flavor, odor or appearance. Is there any thing which will fulfil these requirements? So long as chemists are not agreed upon the real nature or constitution of the bony structures of the body, it certainly must be a fruitless task to endeavor to manufacture an artificial substitute for the natural product, and moreover, the cellular structure of bone can never be successfully imitated. It is more than probable, therefore, that bones will in the near future form the staple food of civilized man.

Taking phosphorous as an example of mineral foods, let us briefly examine the effects of a famine of phosphorous. If it is conceded that phosphorous is a necessary nerve food, it follows that the absence of it means nerve starvation, and a consequent proportionate inability to perform any work requiring nervous energy. Beginning with fœtal life, we would naturally expect that the results would be seen in imperfectly developed, weakly children. Such doubtless would be the consequence but that there exists in the osseous structure of the mother an ample store from which the fœtus can draw its supply. In growing children we would expect to find a deficiency of the osseous structures, with nervous debility manifesting itself in various ways, amongst others, an increasing inability to do school work. Passing along a little farther we find (especially among the females) children breaking down before they are well grown. They have the years of youth with the diseases of old age.

Among adults various forms of nervous weakness become manifest (the neurasthenias of Beard), and in childbearing women there are in addition the evidences of direct absorption in the teeth and alveolar process. Each of the tissues of the body shows the effects of the absence of the proper nerve food. The starved nerve tells its tale of starvation through the language of a neuralgia. Aching and enfeebled muscles remind us of slowness of tissue repair, eruptions on the skin and catarrhs of mucous membranes show diminished nerve power in the tissue. Decaying and loosing teeth become evidences of unhealthiness or of the absorption of the osseous system. Thus will each tissue unmistakably demonstrate the condition of starvation in which it finds itself.

Man certainly enters upon life as a carnivorous animal, living upon animal food in a liquid form, milk. If, during the early months of his existence, gastric or intestinal irritation should come on, so that milk will disagree with him, passing through undigested or producing unpleasant symptoms, then will the expressed juice of beef be found to be the best nutriment that can be administered, not excepting white of egg.

If the child is permitted to follow the bent of his own inclination, his next dietetic step will be to meat. It is rare indeed to find a child who will refuse meat, most of them take to it ravenously, not unfrequently eating it raw by preference, but the child is coaxed or punished out of this natural taste, and "*nolens volens*" becomes more or less a vegetarian, generally a little more.

While the strength and the robustness of vigorous manhood are upon him a man tolerates this vegetable diet, but sooner or later there comes a time when the organs lose their power of digesting these substances, and a more generous animal diet is required to stimulate and invigorate the decaying man.

Finally comes the stage of senile decay, when a little milk or beef juice or nourishment of that class is all that will be tolerated. The dietetic circle is complete; second childhood is here, and the individual sinks slowly, peacefully and unconsciously back into the earth whence he came.

Such would be the course of human existence could it run smoothly and uninterruptedly to its natural end, but accidents and diseases, the latter being in a great degree the consequences of our hygienic transgressions, more frequently terminate what would otherwise be a long and perhaps useful life.

Parkes, p. 206, makes by implication a statement disparaging to the effects of a purely animal diet. When speaking of the possibility of substituting carbohydrates for fats, "if so," says he, "a man could live in perfect health on a diet composed only of fat-free meat and starch with salts and water, just as he can certainly live (*though perhaps not in the highest health*) on meat, fat, salts and water." If now we turn to the personal experience of Sir Francis Head and others quoted by Pavy, p. 307, we find statements quite at variance with this idea of Parkes'. He says: In "F. B. Head's Journeys Across the Pampas" (page 307, op. cit.) is an interesting description of the Indians who inhabit the vast unknown plains of the pampas. "In spite of the climate, which is burning hot in summer and freezing in winter, these brave men, who have never yet been subdued, are entirely naked, and have not even a covering for their head. They have neither bread, fruit, nor vegetables, but *they subsist entirely on the flesh of their mares*.[1] The ground is the bed on which, from their infancy, they have always slept. The flesh of mares is the food on which they have been accustomed to subsist."

Sir Francis Head, when crossing the pampas, got tired at first with the constant galloping, and was forced to ride in a carriage, after five or six hours on horseback. "But after," says he, "I had been riding for three or four months and had lived on beef and water, I found myself in a condition which I can only describe by saying that I felt no exertion could tire me Although I constantly arrived so exhausted that I could not speak, yet a few hours' sleep upon my saddle, on the ground, always so completely restored me that for a week I could daily be upon my horse before sunrise and could ride till two or three hours after sunset, and have really tired ten or twelve horses a day This will explain the immense distances which people in South America are said to ride, and which I am confident could only be done on beef and water" (op cit, 307) Again, "We find a people living between the twentieth and fortieth parallels of latitude in the Argentine Republic, known as Guachos (the half white inhabitants of the pampas) They are a mixed race, of Indian and Spanish blood, who are employed at the ranchos, or great cattle stations, and spend the greater part of their time on horseback in hunting the half-wild cattle which roam over the wide grassy plains extending from the Atlantic coast to the foot of the Andes * Those people live entirely on roast beef with a little salt, scarcely ever tasting farinaceous or other vegetable food, and their sole beverage is mati, or Paraguay tea, taken without sugar" (Odontological Society's Transactions, Vol II, New Series, p 44, op cit 307)

---

[1] The italics are mine.—R. J. N.

That man in his natural condition is a carnivorous animal, is evidenced by prehistoric finds in caves, in the kitchen middens (kjokken moeddings), in mounds, tumuli or burrows or tombs, and by cromlechs, or dolmens, which have already been discovered and explored in various parts of Europe, and which doubtless exist in various portions of the world During the many thousands of years embraced in the paleolithic period, the life of the human dweller upon this globe was that of a hunter, and his food the result of the chase Not only had he not learned to till the ground, but he had not even arrived at the domestication of an animal of any kind ("Dawn of History," by C F Kearz, A M, p 15, et seq) "According to Dr Hyades, who has lately returned from Tierra del Fuego, whither he was despatched on a mission by the French government, the Fuegians are the lowest human beings in the scale of existence The language contains no word for any number above three, they are unable to distinguish one color from another, they have no religion and no funeral rites, and they possess neither chief nor slaves Their only weapons are bone pointed spears, they grow neither fruit nor vegetables, and as their country is naturally barren, they are obliged to live entirely on animal food But they are not cannibals, they ill-treat neither their women nor their old people, and they are monogamous" (*Brit Med Jour*, March 7, 1885, p 482)

Dr Livingston says "When the Makololo go on a foray, as they sometimes do a month distant, many of the subject tribes who accompany them, being grain eaters, perish from sheer fatigue, while the beef eaters scorn the idea of even being tired" (Pavy, p 340) Dr Pavy's own opinions on this subject cannot be better expressed than by the following quotations "Lean meat has always entered largely into the diet for training, and experience shows that it contributes in a higher degree than other food to the development of strength and energy If we look at the lower animals and compare the carnivora with the herbivora we notice a striking contrast in their muscular vigor and activity It has been ascertained physiologically that animal food disposes to the removal of superfluous water (xx) and fat, and makes the muscles firm and rich in solid constituents The accounts that are furnished by travelers point to the aptitude of a meat diet for increasing the power of performing muscular exertion" It is asserted that the length of the intestine in a full grown ox is 150 feet, while in the man the length is 32 feet In proportion to the length of the animal this would give in round numbers for the ox 15 feet of intestine to 1 of length for the man 5 to one, while the lion is set down as having but 3 to 1 The development of the cecum in man also shows a leaning toward the carnivora" (Pavy, p 317)

The action of the jaws in the human being during mastication is not that of grinding, as in the ruminantes, and is therefore unfitted to reduce vegetable fibre to a pulpy condition, such as would render it digestible by human digestive organs of ordinary activity On the contrary, the motion is one rather of compression and more suited for cutting and squeezing, and is the one likely to prove most efficacious in the mastication of meat

Among the teeth the carnivorous teeth predominate The simplicity of the digestive apparatus is that of the carnivora "In the bile of the carnivora and of man the golden red color is caused by bilirubin ($C_{16}H_{18}N_{2}O_{3}$) In the herbivora the green tint is due to biliverdin ($C_{16}H_{18}N_{2}O_{4}$) Bile salts are chiefly *sodium glycocholate* and *taurocholate* In the bile of the herbivora glycocholate is in excess, in that of man and carnivora, taurocholate" (Dr J C Draper)

In man also the chemical constitution of the urine resembles more that of the carnivora than that of the herbivora Those interested in the antiseptic action of the bile salts will find a very interesting résumé of the subject in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, March 21, 1887, p 325 The relatively great length of the bowels in the herbivora would indicate that the "succus entericus" is much concerned in the digestion of vegetable foods, hence it would follow that while the herbivora might readily live upon animal food, it would be difficult for the carnivora to subsist upon a vegetable diet In the herbivora there would simply be an excess of digestive powers, in the carnivora there would be a want of it, and so we find that in its efforts to accommodate itself to its changed diet, the originally short intestinal canal of the wild-cat has been lengthened in the domesticated animal

From what has been brought forward it seems self-evident that the most natural place in which to seek for our mineral foods is among the animal structures themselves In the bone we find ready at our hand all the elements required, each in its due proportion, and we need no longer trouble ourselves with the dispute going on among chemists as to the precise condition of combination in which they exist The bone waste and dust caused by sawing and other mechanical operations in the manufacture of various articles from bone, are used to feed cattle and poultry (*Scientific American*, January, 1885, p 551) "Dadd's Veterinary Medicine, p 370, suggests use of 'flour of bone' for dogs in need of phosphates English patent No 891, of A D 1862, describes a food for dogs and other animals in which bone flour and barley meal are ingredients "

Of course it may be objected there is not of necessity any parallelism between the effects of such food upon animals and upon man "Animal nitrogenous substances appear to be more easily digested than vegetable " And as with nitrogenous substances so it is believed that animal fats are more easy of digestion or preparation for absorption than vegetable, (mineral fats or oils are entirely outside the discussion, as they come more within the domain of therapeutics,) the vegetable oils being usually more or less cathartic It is not reasonable to suppose that the mineral matters will form an exception to this rule But, *on the contrary, analogy would lead us* to argue that whereas, animal products of other kinds are most easily digested by man, that, therefore would bone be the most suitable form in which to give the mineral food

In all chemical operations upon solid matters the rapidity and ease of reaction is increased in proportion to the minuteness of the subdivision, this rule holds good also in its application to the digestive process, and therefore it was not for a moment imagined that solid particles of bone of any considerable size could be either ingested with comfort or digested afterwards There may have been a time when the human stomach was equal to such a performance, but it certainly is not in this our day It is essential therefore that the bones should be reduced to the smallest possible state of mechanical subdivision, to an impalpable powder, as a condition precedent to their employment as a food adjunct

Bone Flour —To obtain pure, fresh, healthy bones in an impalpable powder was a problem which seemed to me most difficult of solution, but the business enterprise of Messrs Parke, Davis & Co came to the rescue, and this firm, at my solicitation, undertook the manufacture, and is now supplying a most elegant preparation, in fact the only one in the market The firm write to me as follows "In this preparation we have employed the cleanest bones that were attainable, and thoroughly cleansed them of all foreign matter, then gradually reduced them to dryness in a low temperature, and finally powdered them in our chasers And we believe that no portion of our process has permitted of the contamination of objectionable features "

Bone flour is not brought before the Association as a medicine, the very nature of the rôle it is intended to fill removes it from the list of remedies, of pharmaceutical preparations proper, and places it among the foods It, from its very nature, is a diet, and its use is intended to rectify one of the dietetic mistakes which has descended to us from past generations and has been faithfully perpetuated by the present with constantly increasing strength and multiplying disastrous results, viz the sifting out of mineral matters from the food, the tendency to live exclusively upon purely nitrogenous and carbonaceous alimentary substances It is intended in some degree to offset the evil effects of the sedulously cultivated taste for a diet composed of sugar and starch in very abnormal proportions

The quantity of bone flour which should be consumed is an important question Pavy says, p 322 "The amount of mineral matter required may be set down at from three fourths ounce to one ounce daily " But he fails to say by what reasoning or upon what evidence he arrives at this conclusion Probably one of the best roads to a solution of this question would be to assume man to be a flesh eating animal and then to give him the same amount of mineral matter which he could receive if he was subsisting entirely upon meat Nothing can be easier than the administration of bone flour Being tasteless and in the state of impalpable powder, it can be given in breads, cakes, soups, or any medium thick *enough to hold it in suspension for a few minutes*

Much remains to be said upon this subject, but the constantly increasing length of this already too voluminous paper warns me that I must reserve the further discussion of this matter to a future occasion

---

THE TREATMENT OF UTERINE FLEXURES BY THE INTRA-UTERINE STEM[1]

BY GEORGE B FUNDENBERG, M D ,

OF PITTSBURGH PA

I desire to make a plea for the more frequent use of the intra uterine stem in flexures of the uterine body *I am convinced that this mode of cure* is not practised as often as it should be, and that it is capable of affording relief in many cases which can be attained by no other method We all know that there is a very general distrust of the intra-uterine stem among the large body of medical practitioners —a distrust which is not born of experience, as it can be proved that at least one half of the regular practitioners of medicine in the United States have not even given the instrument a single trial

Their disinclination to use it arises simply from the reports which are given in the leading text books on gynecology, in which the dangers and disasters following its use are more emphatically referred to than the advantages to be derived from it I am quite certain that the opinions expressed on this subject by certain of our leading authors are not the outcome of impartial, painstaking and numerous trials, but are much rather to be attributed to a natural desire to guard the less expert part of the profession from the supposed dangers attending the method, and I believe that many of the bad results which have attended the practice have arisen from one or all of the following causes 1 To its application in improper cases, 2 To its introduction without preparatory treatment; 3. To the attempt to straighten a chronically flexed womb by the introduction of either a rigid or elastic stem.

---

[1] Read in the Section of Obstetrics and Gynecology at the Thirty Sixth Annual Meeting of the American Medical Association

This fear of the stem has induced practitioners to attempt the cure of flexures by manifold devices, many of which have enthusiastic supporters. In an excellent paper read by Dr. W. D. Kearns, at a late meeting of the Pittsburgh Obstetrical Society, the cure of flexures by instrumental dilatation was very highly praised. He stated that he had cured many cases by dilatation, and the same result was stated to have followed its use in other hands.

I have much faith in rapid instrumental dilatation in various conditions of the womb, having practised it freely during the past fifteen years. I have never seen any cellulitis or other form of danger follow its use, except in a single instance, in which a sharp attack of cellulitis followed its injudicious use in a patient with whom a former attack yet lingered in a latent form. I esteem it so highly that I shall never again incise the os internum so long as I can, by divulsion produce the same result without an open wound, and consequently without any danger of hæmorrhage, cellulitis or septicæmia, for, the mucous membrane being elastic and distensible in a high degree, suffers an extreme degree of tension without rupture. I do not think I have ever cured a decided flexure by dilatation, and, indeed, how a dilatation of the cervix could remove a bend in the uterine body seems rather difficult to understand. Neither have I cured any chronic cases by pessaries or by the genu-pectoral posture. By both these measures the fundus can be raised to a higher plane in the pelvis, but neither are capable of *unfolding* or straightening the uterus.

I am afraid that many of the supposed cures of flexion by dilatation are only apparent. It is well known that many of these cases are accompanied by stenosis at the os internum, and, therefore, dilatation, which removes the stricture and its train of symptoms, is credited with the cure of the flexure, whereas it only removes one of its complications. Slight and recent cases may be cured by intravaginal support, and, perhaps, by dilatation, but when we meet with old, retort-shaped flexures, in which the uterus has *grown* into distortion, we have but *one* remedy, and that is the *intra uterine stem*.

The use of the stem has been subject to the same changes of opinion which have characterised many other methods of treatment. From the time when Prof. Simpson, in 1848, gave his first report of its use, up to the present period, it has been both lauded and denounced in unmeasured terms. It would require more time than can be given now even to mention the names of those who have introduced new shapes and new material. At a single meeting of the London Obstetrical Society, in 1873, three gentlemen presented each a new form of the instrument. At the present time the greatest diversity of opinion exists among our leading gynecologists. Prof. Thomas thinks it should only be employed in rare and obstinate cases. He believes that a large proportion of cases can be relieved by vaginal support. And I have no doubt but that he does relieve his cases in many instances by his admirable tact in the use of pessaries, but to relieve the most urgent symptoms by vaginal support is not to cure the flexure, and generally compels the patient to wear an instrument during the continuance of her menstrual life.

Dr. Goodell, who formerly said, ironically, that the intra uterine stem was a very good instrument indeed —*to watch*, now says that a riper experience has wholly changed his views, and that there are many cases which can be satisfactorily treated in no other way.

Dr. Emmett denounces both the use of the stem and the use of dilators in the treatment of flexures as irrational and dangerous. He prefers, even in flexures of the body, surgical interference. He states, however, that he has cured retroflexion by the long continued use of hot-water injections, by hot baths, by blistering the cervix in order to deplete by the watery discharge, by daily glycerine dressings, by careful attention to the bowels and to the general condition. And, in addition to all this, he directs that by degrees, as the tenderness subsides, the fundus should be lifted, day after day, as far as possible by the finger in the rectum. He states that he has succeeded, by these means, after months of daily manipulations, in restoring the uterus to position. I have no doubt but that this method will succeed in a certain number of recent cases, but even if a case were cured now and then by this tedious method, the questions would remain—How many would *not* be cured by it? How many patients would submit to such treatment long enough, or would be in circumstances to undergo it? If, then, we have a method which will render such long continued manipulations unnecessary, and which, with proper precautions, can be proven to be as safe as any other, why should we not adopt it? That occasional trouble may follow the introduction of the stem cannot be disputed, but when intelligent precautions are taken, the treatment will compare favorably with other methods, and will far surpass in safety any surgical operations.

A stem should never be introduced into a congested womb without previous treatment. Even the successful application of a vaginal pessary requires this. If there be considerable tenderness upon pressure, or if there be evidence of previous cellulitis, or any other lingering chronic inflammation of the pelvic tissues, a preparatory treatment is absolutely necessary. If the uterus be heavy, and sinks into pelvis, it should be lifted up by glycerine dressings, keeping the patient in the recumbent position for a number of days and saline aperients given to deplete the pelvic tissues. When the fundus has remained in the hollow of the sacrum for some length of time, considerable congestion almost invariably exists, attended with complicatious due to obstructed circulation.

I have no doubt you are all familiar with various kinds of stem pessaries. It is unnecessary to go over the list of the different kinds that have been devised. Their name is legion, composed of wood, rubber, metal, glass, and porcelain, some stiff and unyielding, some elastic and furnished with springs Last and least, a split stem, which when introduced springs apart and so holds itself in place whilst dilating the uterine cavity I hold that in all these stems the proper principle is violated The chronically flexed womb cannot be straightened by force, nor even by a constant propulsive force as given by a spring The only successful method that I know consists in gaining the desired position by short steps, with considerable intervals of *rest* between them, giving time thus for all irritation to subside, and the newly awaked nutritive forces ability to build up the long innutrition of the flexed point I do not doubt that many chronic flexures can be cured in this manner, not excepting many congenital cases, for the building up of lost tissue can only be accomplished when entire absence of irritation and absolute rest are obtained, conditions which cannot exist when an unceasing irritating force is in operation The result of efforts to forcibly straighten the womb is in no sense curative, for the unceasing irritation calls into action the formative power of the organ, and a hyperplastic deposit occurs, in the walls of the uterus, which becomes heavier and congested, a condition being thus established more formidable than the one attempted to be removed, for hyperplasia is not nutrition I show you here a form devised by Dr *Chadwick, of Boston You will observe that this* delicate stem is elastic, and in this differs from most others Introduce a stem like this, and if the womb has even a slight tendency to return to its flexed condition, the result will be that sooner or later this stem with its minute bulb will have buried itself in the soft and infiltrated walls of the uterus, but if the tendency to flexion be strong, as is usually the case, there will be hæmorrhage and such an amount of irritation, in a short time, as to compel its removal Apart from these objections, the instrument has good points If one wished to straighten a twig which had grown into an acute bend, he would not attempt to force it into a straight form at one effort but you would apply such a moderate force as would compel the twig to *grow* straight And the same practice lies at the foundation of the treatment of flexures with the uterine stem

I have also an instrument which I have used with much gratification, and in the application of which the principle just announced is observed It is made of hard rubber, and when heated can be bent into any desired curve The part which rests in the uterine cavity is shaped like the cavity of the womb, flattened antero-posteriorly, and has a narrow stem passing through the cervix and os internum It has a slight flange which tends to retain it in the uterine cavity The button below is so large that it cannot pass into the cervical canal The depth of the uterus is ascertained by the probe, and the stem is always one-fourth of an inch less in length than the measurement given by the probe In using this instrument, I never pass *it straight* When first introduced I bend it into the shape of the flexed uterine canal, making no attempt to straighten the the flexure until tolerance of the foreign body is established It is then withdrawn and its exact curve outlined on paper It is now bent to the slightest possible extent, lessening its curve by the aid of the outline, so that the lightest possible impression is made upon the uterine wall It is now re-introduced, and after a variable interval, generally two or three weeks, is again withdrawn and bent in the same manner until the desired position is gained Thus no force is used, no continued irritation produced, and nutrition *is not prevented by irritation*

In regard to the various methods for retaining the stem, the ingenious plan of Dr Chadwick is in many cases excellent This consists of a wire hook attached to the button and embracing an elastic ring pessary But I have found that in a large majority of cases the curved stem will be retained when a rigid or elastic one would be thrust from the uterine cavity I will say that I do not advocate the indiscriminate use of the stem in all flexures There are many which, as they produce no inconvenience, should not be treated at all There are others which cannot be successfully treated in this way on account of complications But there are left yet a large number which are best treated by the stem

I have used the stem in at least fifty cases, and have had no alarming results I have at present four patients who are wearing them, one of them has worn this pattern continuously during the last eighteen *months, and has never suffered any inconvenience* from it She has an intra mural fibroid which drags the fundus down into an antero-lateral position The instrument has come away several times at the menstrual period, and she has always come immediately to have it replaced, as she cannot walk comfortably without it

In a discussion on a paper read by Dr Van de Warker before the American Gynecological Society, on the intra uterine stem, Prof Thomas, commenting upon the dangers attending the practice, remarked that it was not surprising that an organ like the uterus, which often resented the cautious introduction of the probe, the injection of a few drops of water, the retention of a slender roll of soft cotton and gradual dilatation by tents, should not tolerate the *stem But there are generally two sides to every* question It is true that in certain conditions of the lining membrane of the womb, the slightest irritations are violently resented, but these are not the conditions that exist in flexures that are chronic Every practitioner who has made intra-uterine applications with the probe or applicator knows with what impunity the most violent caustics may be applied in chronic affections of the endometrium, such as nitrate of silver and nitric acid An applicator, wrapped with cotton, may be dipped in one of these solutions and applied to the entire lining membrane of the womb and moved about freely in its cavity without producing any pain whatever Such applications to a womb with normal nerves, not blunted in their sensibility by long continued congestion, would produce not only exquisite pain, but most probably dangerous inflammation When writers fail to make these distinctions they miss the mark widely

In conclusion, I have only to say that the disrepute into which the intra-uterine stem has fallen, is largely owing to the fact that the proper principles which should govern their use have not been regarded. We need not be surprised when violent inflammations and intolerable irritations follow the hap hazard use of the stem. We should only be surprised that no greater mischiefs occur under such methods.

A FUTURE FOR PULMONIC SURGERY.

BY E. WYLLYS ANDREWS, A.M., M.D.,

MERCY HOSPITAL, CHICAGO.

The coming triumph of antiseptics, if we may hazard a guess, lies in the perfection, or more properly the creation, of the science of pulmonary surgery. I say creation of this branch, because so little has the subject as yet been investigated, that we do not even know at present the most elementary facts in it to any certainty. So few experiments have been made, and so few cases reported, that practically a surgeon who now undertakes an operation upon the lungs has to base his hope of success upon theoretical considerations.

But that on theoretical grounds a large number of cases of diseased lungs could be benefited by surgical treatment were we once assured of its being safe and justifiable, no one will doubt. If, also, operations through the pleuræ are found to be safer than through the peritoneum, we may set out with the hope that a sufficient boldness will break down our present conservatism and lead us to triumphs more signal than those achieved in abdominal surgery in the last decade.

This subject is to be considered in three aspects, viz.: From the *a priori* standpoint; *secondly*, from an experimental standpoint, the view obtained from laboratory experiment; and, *thirdly*, from a clinical standpoint so far as any cases are at hand for collation and comparison.

A priori then, in the first place, what is the effect of a puncture of a lung? We may thrust into its substance an aspirator or other small pointed instrument with great impunity, as we can in most other parts of the body. In case of aspirating the lungs for purposes of diagnosis, I have seen blood oozing from the lips, showing that both an artery and a bronchial tube of appreciable size had been wounded, and yet not the slightest reaction or local symptom followed. Gun-shot wounds of the lungs are fatal or otherwise not in proportion to the amount of tissue injured, but rather according to size of bleeding vessels, the injury to the adjacent organs and other accidental facts in the case. Shock and septicæmia are not such important factors as in wounds of abdominal organs and parieties. Considering the extreme liability of gun shot wounds to injure some one or other of the numerous great vessels or vital organs of the thorax, it is surprising how many cases of wounded lungs recover.

A little boy in Chicago was shot through the right lung and spinal column not long ago, and although permanent paralysis of the lower extremity resulted, the local symptoms indicated nothing more serious than a temporary circumscribed pneumonia, which had disappeared before I had him under treatment for the paralysis. I saw the patient of another practitioner, brought here from Colorado, who had received the bullet from a carbine at short range near the right nipple. At first recovery was prompt, although the lung was penetrated. After reaching Chicago an abscess formed at the lower border of the right scapula. I was present at the time this was opened, and saw taken out of it a large conical bullet and a round piece of his woolen shirt, both of which had passed entirely through the right lung. The patient then rapidly recovered.

It might seem, therefore, from this and thousands of other cases which have been gathered in military statistics that wounds of the lower and outer parts of the lungs, being further removed from danger of opening large branches of the pulmonary veins, are not *per se* a great source of danger to life. The reason of this I take to be the fact that the vital nervous connections of the lung tissue itself is not so intimate as is that of the intestinal canal and peritoneum. The thoracic organs, therefore, are more tolerant of interference than the abdominal. It may seem paradoxical to say that the pulmonary function is less closely bound up with the nervous sympathies than that of alimentation, seeing that the respiratory action is such a vital one. What I maintain is, however, that this function is less dependent upon the integrity of the visceral tissue itself than in most other organs. The terminal motor filaments which control respiration are not in the lung tissue at all, but in the muscles, either the diaphragm or those outside the chest altogether. The lungs themselves are supplied with few sensitive nerves, so that they seem rather passive, collapsible receptacles controlled by influences originating outside their own structure, responding to the needs of other organs rather than their own. A severe application of cold to the skin will cause more excitation of the lung, than a wound of its own structure. An extensive superficial burn will cause more embarrassment to respiration than the filling of one pleural cavity with air or pus. How different is this apparent tissue insensibility from the highly sensitive alimentary canal, where the slightest irritation causes severe reaction, and if long continued, lights up a fiery general inflammation or else causes shock and collapse!

These are some of the theoretical ideas which have occurred to me, and possibly to others, to explain why injuries to the lungs often produce so slight general effect, and which lead us to hope for immunity from risk in performing operations upon them. Of course we are not to forget, what, I need scarcely call attention to, that the comparative smallness of the area of a single pleura is an important factor in our calculations of the risk of opening it, and also the other obvious fact, which it seems superfluous to mention except for completeness, viz., that only one lung would be treated surgically at a time, so that respiration need not be impaired to a dangerous extent. That the pleuræ suppurate easily on being exposed to the air every one knows. In operating under antiseptic precautions, however, this is readily to be avoided, as will be seen from the cases related. Even when suppuration does occur it is not markedly dangerous. Frequently patients with empyema are seen walking about and only semi-invalids. But this is theorizing, and now,

Secondly, for the experimental tests we must look chiefly abroad. In 1873, W. Koch, of Russia, began experiments to test the susceptibility of the lungs to various surgical procedures. He found that when the lung of a dog was pierced at a number of points at one sitting scarcely any pain was felt. There was no reaction, no impairment of respiration or digestion. On examination some weeks later scarcely any scar could be found. This reminds us of the fact stated by D. Hayes Agnew, that in post mortem examinations the path of a bullet through the lungs is sometimes marked by no visible cicatrix. Injection of tincture of iodine into the lung tissue is also a proceeding free from danger, but this produces a limited consolidation and conversion of some portions of its substance into connective tisssue, no reaction follows, no pain is felt except when the chest wall is being punctured, there is not even a cough unless the fluid gets into a bronchial tube. In Koch's opinion, therefore, two things are demonstrated:

1. The lung is insensible (or indolent) to wounds, and there is little or no reaction. This, he thinks, explains why gangrenous parts of a lung sometimes separate and the patient recovers without any dangerous symptoms.

2. Portions of a lung may be destroyed by the injections mentioned, or by galvano cautery, without killing the animal.

Of course, from these premises, the conclusion to be derived is, that in the human subject we may use such measures to destroy infecting foci of tubercular or other disease.

Gluck has gone farther than W. Koch, and attempted the actual opening of a pleura and extirpation of portions of a lung. One entire lung of a rabbit, in his first experiment, was ligated at its root and removed. Out of a considerable number of cases only two deaths resulted, and these were accidental, since the phrenic nerve was inadvertently destroyed. The rest recovered, and upon being killed and dissected later, little or no mischief was found to have occurred in the remaining lung, which was now doing double work. This, of course, was an important part of the experiment. One animal, after a year had passed, was still healthy.

Another series of experiments of similar character was made upon twenty rabbits and dogs, as in the last case, with antiseptic measures, and close compressions afterwards to assist in collapsing the chest wall. Of these a few only died, of pleurisy and pericarditis, the greater number recovered, and without dyspnœa. In these cases it was shown that secondary hæmorrhage does not follow the removal of a part or the whole of a lung, as none of the deaths were from this cause. There seems to be some liability to pleurisy upon the opposite side, for what reason it is not easy to say.

Prof. Schmid, however, has made still more practical experiments by resecting not the whole but a part of a lung, the only extirpation at all likely to be performed upon the human subject, and not so simple an operation. Here the method of operating was as follows: The dog was washed, shaved over the chest wall, and anæsthetized by morphine and ether. A part of the fourth or fifth rib, he does not seem to care which, was resected and the pleura divided, so that a piece of the lung could be drawn out through the wide incision with fingers or forceps, it being now, of course collapsed. Then a sort of ligature *en masse*, or compressure, was employed by transfixing the lung with a needle and applying pressure, by means of a catgut ligature, below the place intended to be resected, in order to prevent bleeding from the part operated upon. Having thus rendered the part bloodless, a wedge shaped piece of the lung was cut out, the large vessels and bronchi united, one by one the edges of the lung wound sutured with catgut, the temporary ligature removed and the lung returned to its cavity, after which the external wound was also sealed up.

Of eight dogs treated in this manner three recovered and five died. There was no hæmorrhage in any case. Empyema followed in four cases. It is assumed by Schmid that these could have been saved by more thorough antiseptics. This is not so evident to me, however, as suppurating pleural cavities occur where there has been no external wound. After such an operation air, highly septic, may enter from the divided cells or bronchi, as in cases of phthisis, where perforation occurs through the visceral pleura, setting up supperative pleuritis.

Schmid has practised the same operations upon the cadaver, without any very instructive results. He proposes that this operation be performed upon persons suffering with abscesses, and also tumors in the lungs, also upon a single isolated cavity of one lung. He also thinks that an infiltrated apex resulting from chronic bronchial catarrh in persons predisposed to phthisis, might sometimes be removed in time to check the disease.

At Dantzig, Block has made similar experiments on animals. He succeeded only in killing all his first animals, but later elaborated a more successful method of operating. The lung is laid bare by means of a horizontal incision, and drawn out, then ligated, cut off, and returned. Block believes that in cases of wounds to the lungs where there is hæmorrhage from large vessels, this method might be valuable, and like Schmid, thinks it could be employed in cases of tumors, gangrene, abscess, and to remove and infected apex.[1]

Thirdly, from a clinical standpoint we are to examine the practical results of lung operation so far as they have been attempted on human beings. The possibility of a man living with one lung, and the compensatory enlargement of the other, is shown by a case in *Virchow's Archivs*. A man whose lungs were supposed to be normal, died of apoplexy, and on *post-mortem* examination was found to have merely a rudimentary left lung of fœtal development and size. The left bronchus ended abruptly in a *cul de-*

---

[1] I am indebted for the above to Dr. D. Ary's translations from the Russian journals.

sac, one inch from the bifurcation, and no air had ever entered the embryonic lung at all. But the left side of the chest was not so much collapsed or filled out by the compensatory enlargement of the right lung and mediastinum. The pericardium was indeed grown fast to the costal pleura as high as the third rib.

This may show, in a measure, what to expect to follow should we ever succeed in extirpating successfully an entire lung in man, as has been done in dogs. And it shows that the loss of the organ is not a dangerous element in the operation. Mosler's first case of operation consisted in draining a large cavity by open incision. It was not sucessful in saving the patient or in much prolonging his life. Another case, but meagrely reported, is that of a man 44 years of age who had a large pulmonary abscess in the lower lobe of the right side, which was opened and freely drained, whether with antiseptic precautions we are not informed. This patient was at first relieved, but subsequently died of suppurative pleurisy. A third recorded case is one of multiple septic abscesses in lower lobe of right lung. Upon opening and draining this abscess great improvement occurred in the general condition, and the hectic diarrhœa was checked, as was also the cough and foul expectoration. These returned, however, as the drainage was improperly cared for, and ultimately the patient died with pleuro pneumonia of the other lung. An abortive effort has been made by Williams to puncture a supposed broncho-ectatic abscess. He afterwards made a second puncture, deriving a small amount of pus, which in his opinion was formed in consequence of the first incision.

Still another case on record is one of a so called gangrenous cavity of the right lung—middle lobe—which was punctured from the posterior side at the angle of the scapula. The patient was almost in collapse at the time. Immediate improvement occurred, and the purulent expectoration ceased. After one week, this reappeared, and the patient was nearly as bad as before, dying upon the twelfth day.

If we examine the cause of death in these unsuccessful cases, we see that in one only was the fatal result caused by the complication usually most feared —pleurisy, but insufficient drainage and lack of boldness were apparently what rendered the operations futile. No drainage of so deep a cavity can be considered perfect without the insertion of a rubber tube of fair calibre, and even with this, unless antiseptic injections large in volume are employed, we are using only half the means in our power to check the progress of the disease. Some have feared, apparently, that injections, as they necessarily must enter the bronchial tubes, might so flood them as to produce asphyxia or too much irritation; but of this it may be said that the injection can reach only where the pus has already reached, and that a little excess or overflow of it will only be expectorated and do no harm. Of course, it should be made mild and unirritating, and its use begun cautiously. On its practical efficacy I will speak presently.

But all these cases of lung surgery have not been so unsuccessful as the earlier ones recorded. One patient, whose right lung contained a large abscess, daily discharging large quantities of fetid pus, was promptly relieved and improved by an incision in the sixth intercostal space, and although he died from other causes a month or two later, it should be regarded as a successful case. I am only able to get a meagre history of this case from D'Arcy, who also describes the following.

A man, 44 years of age, who had suffered severely from dyspnœa and purulent expectoration, was found to have in the anterior surface of the right lung a cavity of considerable size, which was diagnosed as an echinococcus cyst. This was treated by opening the thoracic wall and freely excising the entire sac (under antiseptic measures, of course), and with complete recovery of the patient.

Drs. Hollister and Fenger have reported cases of abscess of the left lung treated by drainage and resulting in recovery.

One of the first instances of carbolized injections being used in the lung itself, was that of an old consumptive, who, by Dr. H. A. Johnson, was discovered an immense collection of pus in the left pleural cavity.[1] After draining away just four quarts from the pleura, it was found that a tuberculous cavity had emptied itself into the pleural sac, so that after a certain amount of warm carbolized water had been thrown in it would rise in the throat and could be tasted. This occurred regularly at each dressing, and caused no inconvenience. The case is of no special interest except as showing the harmlessness of throwing the solutions into the lungs and bronchi themselves.

The case of Henry Cordes, 28 years of age, who is now still under my observation, is an interesting one as being a case of real abscess of the lung relieved and practically cured by surgical operation and after-treatment. In July, 1882, this patient was affected with fever and night sweats, followed not long afterward by muco purulent expectoration in constantly increasing quantities. Dr. N. S. Davis, into whose care he finally came, was convinced that he had located a cavern near the posterior wall of the chest on the left side, and considered it not of tuberculous origin, in which the sequel shows that he was correct. Dr. Davis placed him under the care of Dr. E. Andrews. As the patient was rapidly sinking into hectic, and was expectorating a pint or more of sputa a day, it was thought necessary to run the risks of laying open the abscess from the back, which was the seat of most pain, and where we hoped that adhesions had already formed to the chest wall.

Upon exploring this point with the aspirator, however, nothing but blood was obtained. Between the fourth and fifth ribs another puncture was made more anteriorly, with the same result. In the anterior chest wall, however, pus was found, and an incision freely made down to it without exsecting the rib. From this opening a large amount of fetid pus escaped, and eight inches of a large flanged rubber drainage tube was inserted. A few ounces of very dilute warm carbolized water were injected, and the patient put to bed, where in the course of the night another pint or more of pus was discharged from the tube The patient now recuperated astonishingly from the disease which had brought him so low, the sputa at once ceased to be expectorated, and the discharge from the tube became almost odorless He sat up on the second day and ate ravenously His night sweats ceased, and he was no longer short of breath About a pint of carbolized water was thrown into his abscess at each dressing, and part of this always made its way into the throat, not causing him inconvenience, but being tasted and spit out, sometimes mixed with pus and sometimes nearly clear, and easily recognized by the odor in his breath He had no dread of this injection, but said it seemed to "clear his throat," In somewhat less than a month the patient was able to leave the hospital, and visit my office daily, the abscess having so far collapsed that little remained but a small sinus communicating with a bronchial tube For months the condition remained the same There was no cough nor pain in the chest An injection forced into the tube came up into the throat without causing more than a momentary cough

---

[1] This man had been declared by a Homœopath in his diagnosis, to have something wrong with his heart and there was something wrong for it was crowded two or three inches away from the point over which he had been placing his stethoscope.

Before this sinus entirely closed, which was almost a year after the operation, the patient had regained his former strength and more than his former weight He is now strong and ruddy, without any symptoms of pulmonary disease, and with only a deep scar and a slight area of dulness to indicate the location of the abscess

The results from so meagre a list of cases are wanting in conclusiveness, but by no means in encouragement, and we may be justified in taking hopeful ground as to the future of pulmonic surgery

6 East Sixteenth St, Chicago, Aug 20, 1885

EPIDEMIC CHOLERA, ITS SYMPTOMS, PATHOLOGY AND TREATMENT

BY FREDERICK HORNER, M D,

OF MARSHALL FAUQUIER CO VA

Sacred and profane history present graphic details of pestilences or epidemic diseases In King David's reign, a pestilence destroyed 70 000 men—a calamity which the Bible asserts to have been a judgment of the Almighty to punish a nation for the violation of Divine and physical laws Thucydides has given an eloquent description of the plague which devastated Attica and the City of Athens during the Peloppone sian War A pestilence which prevailed between the years 1345 and 1350 is said to have been so deadly that two thirds of the human race perished In the city of London 50,000 dead bodies were buried in one graveyard It was called the "Black Death"

The mortality of epidemic cholera has never attained to the high figures of such precedents, doubtless for the reason of its modern origin, and because Christian civilization has contributed to mitigate the ills of human life, and medical art is better able to prevent and to cure disease Cholera, from χυλη and ρέω, two Greek words signifying literally a flow of bile, is a misnomer, since the disease does not consist in a morbid and excessive discharge of bile Dr Johnson, who treated the cholera of tropical climates, declares that "in all cases at first there is a diminution, and in many cases a total suppression of the biliary secretion, and the watery discharges continue until the disease takes a favorable turn," adding that in all fatal cases there is an absence of bile in the stools

This disease had its origin in India, along the Ganges, in 1817 In 1820 it extended to China, in 1823 to Astracan, on the Volga, in 1829 to Russia, in 1831 to Mecca, to Cairo and Alexandria, and subsequently, in 1832 to London, Paris, and to the United States The medical authorities at Calcutta attributed, as causes of the disease, extreme heat and drought, followed by heavy rains, and the use of unwholesome food, such as melons, cucumbers and raw vegetables The serfs of Russia, who lived in low, damp and filthy houses, and who habitually indulge in intoxicants, were the greatest sufferers, the same remark was true as to the lower classes in Europe and America The troops of large armies, as well as the pil grims who visited Mecca and to worship Juggernaut, overcome by long marches and journeys, readily contracted the disease, many dying from fear

Both German and English physicians are of the opinion that the epidemic cholera of that period was of spontaneous origin and not imported It was then denied to be transmissible and to be contagious, since neither quarantine regulations or cordons availed to prevent its introduction to neighboring localities The removal of the sick to suitable hos pitals was urged and adopted as a precautionary measure to ensure a better chance of life to the patients, as well as physicians and nurses As an endemic the disease the disease is a common malady, since cases of sporadic cholera constantly occur in warm climates, due to errors in diet and a stomach overloaded with acrid and undigested food Indeed, some authors are of the opinion that its epidemic character does not invest it with any speeific characteristics save in degree, not in kind During the latter part of the summer of 1854, two cases presenting all the symptoms of malignant cholera occurred in the writer's practice, and he is able to recall, also, another which occurred at the Norfolk Navy Yard in 1857, in the person of Lieut Rob't B Pegram

Mr Lizars, of Edinburgh, says of the disease which prevailed in that city in 1831 "It can hardly be considered to be contagious, since dissections several hours after death were performed without propagating cholera, which appeared simultaneously all over the suburbs of the city, without any communication of the subjects of its attacks" That it is infectious is more probable The hypothesis first advanced by Sir Henry Holland of insect life as a cause of the disease, is now fully confirmed by the brilliant discoveries of Dr Koch, who asserts that the infection is not conveyed by the air, but by the absorption of the microbes, comma-bacilli, in eating, thus introducing them into the digestive canal This is done both by means of drinks and of solid food Hence he advises, where cholera prevails, the closure of the wells, and that people drink water which has been boiled, or comes from points distant from the infected centres, or waters slightly mineral, and that food should be cooked at a high temperature. He adds, "The microbe dies when exposed to a high, and especially a dry temperature. It is solely transmissible by direct dejections or articles soiled by them; the first precaution, therefore, is to expose the linen of patients to dry heat or carbolic acid, somewhat strong, for the microbe cannot live in strong solutions of carbolic acid or in great dryness."

The premonitory symptoms of cholera are præcordial distress, weakness, looseness of the bowels attended with griping, followed by nausea, vomiting, diarrhœa, and headache. The attack usually begins at night or after exposure to a hot sun, fatigue, and free indulgence in meats and drinks. A lull occurs after the bowels appear to have been emptied of their fæcal and solid contents; the skin is cold and corrugated, and of a livid hue; the eyes are sunken; the pulse from the first is small and quick; the blood, if drawn, is dark colored and flows slowly; the fluid matters ejected from the stomach and bowels usually contain no bile and have no fæcal odor, and consist of a turbid whitish liquid, resembling water in which rice has been boiled. Favorable symptoms, during the first stage, are marked by cessation of vomiting and purging, and a reappearance of bile in the dejecta. Death may occur within the first twenty-four hours.

The occurrence of the second, or algid stage of the disease, is marked by an aggravation of all of the above-mentioned symptoms. The patient has a sharp and anxious countenance, an expression pathognomonic to the eye of an expert; the pulse becomes small and feeble; the skin is blue and cold to the touch, and the fingers are shrivelled and sodden like those of a washerwoman. The voice is unnatural, and to add to the intense suffering, there is dysuria, and cramps of the muscles of the thighs, legs, and abdomen. Dr. Cragie says: "The cramps were observed chiefly in the gastrocnemius and soleus of the legs, in the biceps flexor of the thigh, in the recti of the abdomen and the adductors of the thigh; the extensor muscles were not affected." Amid all this mortal conflict in the body, the mind and senses remain undisturbed almost to the latest hour of life, though the victim seems totally unconscious of the rapid dissolution which threatens him. "Walking cases" have been noticed, as occur during an epidemic of yellow fever. The patient is able to walk about, fails to apply for medical aid and dies suddenly.

It is important to remember that the first indications of an attack of cholera are twitchings of the fingers and toes, along with immediate sinking of the circulation. The patient sometimes lingers in a pulseless state for a long time before death actually occurs. Hence the danger of too early burial during the prevalence of epidemic cholera, but which may be avoided if there has been observed an increase of temperature of the body, confined to the head and trunk, taking place just before death. As occurs in smallpox, typhoid and puerperal fever, there is a peculiar fetid odor or exhalation from the skin and breath of a cholera patient. When death does occur, it is sometimes preceded by violent spasms of the abdomen and extremities, deadly pallor, shrunken features and icy coldness of the entire body, thus constituting an example of spasmodic or Asiatic cholera.

Pathology.—In this connection, it may be premised that the late Professor W. E. Horner found that the lesions exhibited by the post mortem examination of the viscera of children who had died from cholera infantum, especially the mucous membrane of the alimentary canal, presented often "an abnormal paleness, and the liver is more or less congested, and of a light yellow or mottled color. The follicles are enlarged, resembling in appearance a sprinkling of white sand upon the surface of the mucous membrane. In a patient affected with epidemic cholera, the blood found in the lungs is always black, the liver is commonly gorged with blood, the bladder empty and much contracted, and the intestinal track presents a blanched appearance, thickened, denuded, and sometimes collapsed. A fluid in large quantities is effused in the lateral ventricles and between the convolutions of the brain, and in the membranes of the vertebral columns and spinal cord." Dr. Kier, of Moscow, in his dissections, discovered signs of subacute inflammation both in the stomach and intestines. As many exponents of modern medical science claim that the cholera bacilli are the source as well as the cause of the disease, the true pathology of cholera yet remains an open question.

Treatment.—With the loss of a few hours and the application of appropriate remedies the chances of recovery are lessened. Annesley, who treated hundreds of cases of epidemic cholera in India, says: "If taken at its commencement it is as manageable as any other acute disease, while if unchecked even the loss of an hour may occasion the loss of life." Absolute rest in bed and absolute diet even to starvation should be enforced; the first rule ensuring freedom from business worry and company, and the second the best chance to administer suitable remedies. For the relief of the stomach an emetic either of ipecac or a solution of common salt, or even tepid water, and subsequently the following prescription should be given:

℞
Hydrarg. chlorid. mite ʒ
Morphiæ sulph., gr. iv.
Bismuth. nitrat., ʒss.
M. Divide into 12 powders; one every two hours.

When the vomiting and purging are relieved, sulphuric acid gtts. x, in a little sweetened water, every half hour, will contribute to restore the normal secretions of the intestines. This acid is also a valuable germicide. Sinapisms should be applied over the epigastrium and on the inside of the thighs and arms. For the relief of the violent cramps and congestion of the lungs and head, when the pulse is full and the temperature not reduced, a bath of hot water should be given, followed by venesection to the extent of twenty or thirty ounces, and the application of leeches when the pain is felt in the epigastrium. This treatment is often sufficient to cut short the disease. As regards the use of the lancet, a full bleeding from the arm in cases of cramp, colic, and in cases of overwhelming shock to the nervous centres and cir culatory system, often contributes to the saving of life During the prevalence of epidemic cholera in 1832, Mr Bell ("Treatise on Cholera") commended the value of venesection except in the intemperate Drs Pennock and Gerhard ("Observations on the Cholera") state when there is febrile excitement, and local pain on pressure, venesection and leeches may be resorted to, with a warm bath This is followed by profuse perspiration They add that the medicine most relied upon was opium, mercurials were not employed in the first stage When the stomach would not retain the anodyne sub nitrate of bismuth, gr ii–iv, every two hours, would often relieve nausea and vomiting "This remedy must be discontinued as soon as the vomiting and spasms cease" The beverages allowed were burnt toast water, iced lemonade, diluted nitric acid fifty drops added to a pint of sweetened water, tea, coffee, and fresh milk Dr Sturm, a Polish physician, recommended the use of warm, nearly hot, water in the quantity of a glass full every half hour

Treatment of the Second, or Algid, Stage—The physician is sometimes called for the first time to prescribe for the patient during this stage of cholera As stated already, in this, as in the first stage, it is all important for the patient to be kept in bed and on a restricted diet, and for the physician, for the sake of his patient and his own reputation, to decide upon a course of treatment most approved and practical The life of the patient depends on arousing the sensibility and exciting the action of the cutaneous nerves, and to accomplish this he should be immersed in a hot bath, 100° F, this was found to be of undoubted value in India and in Europe during the epidemic of 1834 The writer has had patients restored from a state of complete asphyxia by being kept in a bath of high temperature for an hour and more A mild emetic may be necessary, either ipecachuanna, sulphate of zinc, or a solution of common salt and draughts of warm water, to clear the stomach, frequently loaded with undigested food After this treatment, calomel and opium should be given in minute doses to restore the natural functions of the intestines and liver

Recurring again to Drs Pennock and Gerhard's "Observations on the Cholera," they state that "during the algid stage of the disease depletion becomes harmful, and especially so if the pulse be much depressed, frictions with warm liniments applied from the extremities towards the central organs, sinapisms to the extremities, and a liniment of ammonia and turpentine applied by flannels along the spine, and opiate injections, alone availed to afford relief If the latter remedy is rejected by the bowels it must be abandoned, because of the danger of adding to the internal congestions and of increasing the existing feebleness"

Alcoholic stimulants, powerful tonics and full diet in this, as in all stages of cholera, are dangerous expedients When the dysuria is relieved, and coincident with it there is free and full discharge from the bowels, the occurrence marks always a favorable turn in the disease

In conclusion, a word may be added with reference to prophylaxcis during an epidemic of cholera As fear is a powerful depressing passion, it becomes the physician to encourage, on the part of his patients and the community, a cheerful and hopeful state of mind If the religious sentiment can be invoked, this disposition will be greatly strengthened Dr G B Thornton, President of the Board of Health of Memphis, commends the use of a cup of strong coffee or some article of food to be taken before visiting the sick Any imprudence of diet may prove disastrous, as occurred within the writer's recollection to the late Dr White, the resident physician of the Pennsylvania Hospital, in 1854 Dr White, on his way to the Philadelphia Almshouse, unfortunately stopped at a restaurant and ate heartily of ice cream, subsequently visiting and prescribing for a number of cases of cholera He contracted the disease and died in a few days

The waste, as well as articles of clothing of a cholera patient, should be carefully disinfected The disinfectants in common use are so well known that it is needless to give a detailed list

---

MEDICAL PROGRESS

MEDICINE

IODOFORM IN GONORRHŒA —DR A OGER, in discussing the use of iodoform in gonorrhœa, refers to its use in solution of glycerine by M Campana in acute and chronic conditions of the disease The best results are attained, however, when it is applied to the diseased parts in a very fine powder In this form Timmermans has obtained excellent results Iodoform being insoluble in water, he suspends, in two and one half ounces of water, sixty grains of the drug rendered impalpable by previous solution in sulphuric ether The mixture being well shaken, a small glass syringe is filled and injection practised As it is important that the iodoform come in direct contact with the inflamed mucous membrane, the urethra should be thoroughly cleansed by urination immediately before the injection is made The patient should lie on his back and the injection be made in a direction nearly vertical, gravity thus causing the powder to seek the lower part of the syringe, and thus favoring its introduction into the urethra when pressure is made upon the piston When the syringe has been emptied, it should be gently withdrawn, and while the meatus is compressed by one hand, with the other careful pressure is made so that every part of the passage is reached by the fluid, and the iodoform thus deposited upon the mucous membrane After four or five minutes the fluid is permitted to escape gradually, in order to avoid the ejection of the iodoform The operation should be repeated at least three times a day

Whatever is the stage of the disease a prompt result is certain, as is shown by diminution of pain—the iodoform evidently acting as an anæsthetic to the inflamed parts The character of the pus is also changed, and its abundance diminished Cure is promptly obtained, in one resulting in five days —*Journal de Medecine de Paris*, July 19, 1885

SURGERY

STRANGULATED UMBILICAL HERNIA—REMOVAL OF SIX INCHES OF SMALL INTESTINE —RECOVERY —MR W H FOLKER reports this case in the *British Medical Journal*, of August 15, 1885 The patient was a married woman, æt 47 years About 12 years ago she sustained an umbilical hernia from a fall

On February 25, 1884, had a return of the symptoms of strangulation, and was admitted to the North Staffordshire Infirmary On admission, the patient, a corpulent woman appeared to be in a most exhausted condition, suffering from almost constant vomiting of a fæcal character She had a large umbilical hernia, evidently not only strangulated, but gangrenous, for even the skin covering it was quite black, and smelt most offensively

Immediate operation was resorted to, the patient being cautiously etherised An incision was made, of the length of the tumor, opening the sac, when a large piece of bowel was found to be quite black, the contents having escaped into the sac through an opening about an inch and a half in length, the omentum and everything within the incision was gangrenous The skin and everything that was sloughing, except the bowel, was first removed, and the cavity well washed out with carbolic lotion, and then the bowel (which was small intestine) was drawn well forward till a sound portion was reached at each side, the inner halves of each portion were cut through and carefully stitched together, with their peritoneal surfaces in contact, the outer half of each piece of bowel affording a secure hold whilst this was being done, these were then removed, and the cut edges secured to the skin, forming an artificial anus The edges of the skin below were brought together by two harelip pins, and the parts dressed with oiled lint (carbolic oil 1 in 20), covered with absorbent wool, a wide flannel roller being applied over all She was ordered to have the urine drawn regularly with the catheter, and to take ice and soda water

February 29th (the day following the operation) The temperature was normal There was fæcal discharge from the bowel opening The patient was looking better, although vomiting, with a fæcal odor, still continued, and she had some little pain A subcutaneous injection of morphia was given, which relieved the pain and checked the sickness The skin over the abdomen was covered with oxide of zinc ointment spread on lint

March 1st The fæcal discharge continued, and the temperature remained normal, although the sickness still persisted, but without any odor Hypodermic injections and dressing were repeated

March 2nd The upper pin was removed, as it was threatening to cut through, the parts being very tense The sickness had nearly ceased Temperature 100 4° The treatment was continued

March 6th She was doing well, the temperature was normal, there was no sickness As the external parts were giving way, the last pin was removed, which caused the skin wound to gape very much, though the edges of the intestines remained perfectly adherent to each other and to the abdominal wall Strapping was used to support and to bring the parts as much together as possible The use of the catheter was discontinued

March 18th The edges of the wound, looking somewhat undermined, were packed with iodoform-gauze This was ordered to be repeated as often as necessary, for, from the constant welling up of fæcal matter, the patient required dressing several times a day This afternoon, an attack of sickness came on, which lasted from 3 o'clock till 6, but was stopped by a draught of morphia and bismuth

April 9th The patient to day said that she thought she was pregnant, as she discovered milk in her breasts She was, therefore, carefully examined, and such was found to be the case

April 22nd I passed a whalebone sound, and left it in for about half an hour Pains came on, but passed off again about midnight The next day, some ergot of rye was given, and early the following morning the fœtus came away

May 10th The patient having now recovered from all effects of the abortion, it was determined to try to close the artificial opening in the bowel, accordingly, at 2 P M, a blade of Dupuytren's enterotome was introduced into each opening of the bowel, and brought very lightly together At 2 45 sickness came on but, under the influence of a morphia draught, ceased towards evening

May 13th There was no pain or sickness I tightened the enterotome a little more, having screwed it up a little on the 10th Flatus passed *per anum* to day for the first time

May 15th I screwed up the enterotome as tightly as it would go This was followed in the evening by very sharp pain, which was entirely relieved by morphia

May 21st The enterotome came away to day (that is on the eleventh day), Flatus passed in abundance, but no fæcal matter yet, *per anum*

May 25th The temperature rose to 101 4°, with some pricking pain and general uneasiness An enema of soap and water was administered, which brought away some hardened fæces and flatus, and relieved all the other symptoms

May 27th In the hope of restoring the continuity of the intestinal passage, and of preventing the fæces from being discharged through the artificial opening, a piece of stout India-rubber tubing, three fourths of an inch in diameter, and about 5 inches in length, was introduced, one end into the ascending, the other into the descending portion of the bowel It was secured at the centre by a strong piece of silk, the ends of which were left hanging from the opening

May 28th The tube was forced out of the wound this morning Dr Hatton reintroduced it, but it was again forced out at 9 P M

May 29th The tube would not remain in, it was, therefore discontinued

May 31st I reapplied the enterotome to day, this was followed as on the former occasion, by pain and sickness, which was relieved by morphia

June 9th The enterotome came away (the tenth day)

June 12th The edges of the opening were brought together by a broad piece of plaster, but without effect

June 18th Hitherto the patient had had no solid food, and complained of feeling hungry, the diet was, therefore, changed to ordinary solid food

June 23rd An enema of soap and olive-oil brought away a fairly natural motion This was repeated on the 26th, when the bowels were freely relieved They were moved again by the natural effort, an hour afterwards, and again a second time in two hours

July 1st I refreshed the edges of the external opening, and brought the parts closely and accurately together, with five deep, and three superficial sutures Solid food was ordered to be discontinued for a few days

July 2nd Fæcal matter was forced through the wound, and in a day all broke down, the stitches were removed, and the discharge was as free as before

July 16th She got up for the first time, the discharge was the same

July 29th On making a digital examination to-day, both ascending and descending portions of bowel were found to be quite free, and of uniform calibre, the slight prominence, the remains of the spur, could only just be felt by the extremity of the forefinger when introduced to its full length An enema produced an ordinary motion Another plastic operation was therefore performed, but with no better result, for in two days the discharge began to force its way through between the stitches

Enemata were now administered every other day, and a fortnight afterwards the edge of the wound was cauterised, in the hope of causing it to contract This was continued for some time, the application being varied from time to time between nitrate of silver fuming nitric acid, and the thermo cautery

September 22nd She had a natural motion for the first time to day, and again on the 29th, but as this did not occur again, enemata were regularly administered, and always acted copiously, but still fæcal matter continued to well up through the wound, although it was reduced to the size of a ten cent piece

At the end of October, wishing to go home, she was discharged at her own request, all the various attempts to close the wound having failed She has presented herself from time to time at the infirmary, but remains exactly in the same state as when she left The remains of the spur could be felt with a probe at about an inch and three quarters from the surface

This is not a case commonly met with, and, as the discussion may perhaps bring forth different opinions as to the treatment adopted, I would first say that, six inches of intestine having sloughed and burst, its entire removal was imperatively required Then came the question as to how the remainder was to be treated The sloughing was so extensive, that I dared not rest content with opening the bowel and leaving it to form an artificial anus by adhesion, as has occasionally been done in inguinal hernia when the bowel was not fit to be returned, and for the same reason I was afraid to attempt to unite the two ends of the bowel together and return it, and therefore decided upon the method of treatment which I have described

When the patient was found to be pregnant, the question of allowing her to proceed to the full time gave rise to some little doubt If pregnancy had been allowed to go on, it would not have been prudent to have attempted Dupuytren's operation, as it might have caused miscarriage whilst the clamp was on the bowel, and possibly have been fatal, and danger was also to be apprehended from the extreme distension of pregnancy, and the straining pains attending it, and, lastly, there was the great delay All this was fully explained to the patient and her husband, and consent was at once given

The application of the enterotome, on both occasions, only caused a little nausea and sickness, which was easily controlled by a dose of morphia, until it was finally screwed up tightly, when some sharp pain was experienced, but was easily relieved The instrument came away on the tenth and eleventh days, which, I believe, is about the average time

The chief point, however, on which I am anxious to hear the opinion of others is, why does the opening not close? and wherein have I been in fault in my attempts to produce its closure? There must be a clear passage in the bowel, both ascending and descending, of at least an inch in diameter, as was proved by the introduction of the three-quarter-inch India rubber tube, the lower level of the bowel is nearly two inches from the surface There seems no impediment in the bowel, or why should fæcal matter pass as it does when an enema is given? and why should it force through a small narrow opening in the upper part, when there is a free and much larger channel on a lower level?—[The report of this case is taken at length, and with the risk of being somewhat tedious, on account of its unusual character, and great surgical interest]—*British Medical Journal*, Aug 15, 1885

DIGITAL TENOTOMY IN PIANISTS —MR NOBLE SMITH, in speaking of this operation, says that the operation as practised by Dr Forbes, of Philadelphia, promises to be one of great benefit to accomplished pianists, as well as to learners In making some dissections on the dead body, with a view to determine the usual position of the slips of tendon which limit the action of the extensor of the ring-finger, I found that these vary very much in different cases, so that it becomes necessary to carefully determine their position by the eye and finger, during movement of the extensor-tendon, in each case before operation I have just succeeded in freeing the ring-finger of the right hand of an accomplished lady pianist, without causing her much more pain than is felt from the prick of a needle Before operation she was able to raise the finger only five eights of an inch beyond the others Directly after the operation, she could raise the finger easily to one-and a-half inch, without the least feeling of loss of control over its action The division was, of course, made subcutaneously, so that only a minute wound was left in the skin, one eighth of an inch in length —[Cocaine has been recently used in an experimental operation of this kind, and with perfect success]—*British Medical Journal*, July 4, 1885

THE PROGRESS OF PHARMACOLOGY AND THERAPEUTICS

Such is the title of the very interesting and suggestive Address in the Section of Pharmacology and Therapeutics, delivered by PROFESSOR THOMAS R FRASER, of Edinburgh, at the late meeting of the British Medical Association The address is the more interesting from the fact that it is the first that has been delivered in this Section of the British Association, as the Section was only founded at the annual meeting in 1884 And the selection of Prof Fraser as the first Chairman of the Section was most suitable in view of the great facilities for pharmacological work in the University of Edinburgh, facilities which are scarcely excelled by those of any institution on the Continent

Professor Fraser commenced by referring to the fact that in the branches which form the subject of his address we have not made so much progress as in other departments That this is true everyone will admit But may it not be due to another fact, that special work in this department carries the investigator somewhat out of the usual line of work which engages the physician? Is it not more true of this than of any other branch of medicine that the worker must have a special training, and a special aptitude for such work? And is it not due also to a third fact, that in order to accomplish anything in this branch the worker must, from the very start, be thoroughly familiar with chemical work? Again, there is another fact of no less importance practical results in pharmacology must depend in great part on our advancement in physiological pathology, and it must be admitted that this has not kept pace with our knowledge of pathological anatomy "To the therapeutist, and, therefore, to the medical practitioner, the progress of physiological pathology is of as great interest as that of pharmacology In the meantime, neither has advanced further than the threshold of its possible development, and, naturally, the benefits which have been conferred by them upon therapeutics are not as yet conspicuously apparent Their development is, for the most part, wanting even in that equality and symmetry which is required for practical application In only a few instances can we find that each has made sufficient progress to benefit therapeutics, as, for example, in some of the applications of the pharmacological action of the nitrites, or of digitalis, or of several diuretics to the treatment of disease"

He utters a word of warning against hasty deductions and generalizations "Patience must also be exercised to enable us to avoid the great danger to therapeutics, a desire to too hastily gain results, which is constantly besetting us It has manifested itself in all ages, in a search after specifics—so called—a search which tends to distract from solid work in pharmacology, where the results are certain to be more valuable and more conducive to the ultimate benefit of therapeutics My remarks have indicated that I regard pharmacology as one of the means by which the great aim of medicine—the healing of disease—is to be gained It is an essential means, and it therefore becomes of importance to arrive at some clear conception of the method by which the investigation of pharmacological problems is best to be effected"

As might be supposed, the two methods which he thinks open to us are The study of the effects produced by remedies administered in disease, and the study of the effects produced when the drug is administered to the healthy animal, or when physiological pathology is applied to pharmacology As regards the first method, Dr Fraser says that "its results are, unfortunately, too apparently unsatisfactory to require any elaborate criticism Even when the problems are of the simplest description, fallacies that are destructive to the scientific value of the results can scarcely be avoided" As an example, sleeplessness and pyrexia are but manifestations of many kinds of departure from physiological conditions, they are only symptoms, which may be due to many different pathological processes, and their precise nature has yet to be defined by physiological pathology It is quite improbable, even on *a priori* principles, that "each of the abnormal processes leading to sleeplessness, or to pyrexia, will be restorable to their normal state by every substance that is capable of producing sleep, or by every substance that is capable of reducing temperature." A better example of the insufficiency of the method of simple observation in disease could scarcely be given. But when the nature of the pathological processes has been defined the pharmacologist should, and in all probability will, be able to produce the substance that will antagonize the pathological process, and restore the perverted function to a more or less completely healthy state.

It is knowledge of this kind that Dr. Fraser understands to be the aim of pharmacology, and to obtain it, those who work in this department must continue the method of research that have founded the science of pharmacology. It is true that even this is a method of observation; but its results are much more certain than when the observations are made on man, especially if he be suffering from disease. "I cannot too emphatically state that it is only by this method that we can ever hope to utilise thoroughly the means so abundantly placed at our disposal for placing therapeutics in a satisfactory position. If it be a worthy object to aim at lessening of suffering, the prolonging of human life, the prevention of premature death, then I say the study of pharmacology by experimental investigation not only requires no apology, but the neglect of this duty imposes a heavy responsibility upon those who place obstacles in the way of pharmacological research." Yet this responsibility has been assumed by every one who is in sympathy with antivivisectionists.

The last point made by Dr. Fraser, and a very important one, is that it is time that the intimate association which has so long existed between pharmacology on the one side, and pharmacy and the physical characters of remedial substances on the other should be severed. This separation has been effected in several of the Scottish universities, in the school at Manchester, and in two or three of the London schools. In this way pharmacology may be taught at a period when it can be properly appreciated by the student. "It deals with perversions of functions produced by active substances and therefore requires some acquaintance with physiology before instruction in it can be intelligently followed." And in order to further the study of this subject, Dr. Fraser suggests that laboratories for investigation should be established in every important medical centre. "Every argument that can be urged in favor of laboratories for physiological or chemical research can be urged in favor of laboratories for investigating the action of remedies; and it is to be hoped, that this want will be speedily removed."

MR. LAWSON TAIT ON THE MODERN TREATMENT OF UTERINE MYOMA.

MR. LAWSON TAIT's paper, entitled "The Modern Treatment of Uterine Myoma," read in the Section of Obstetric Medicine at the recent annual meeting of the British Medical Association in Cardiff, is interesting and suggestive.

The first point of Mr. Tait's paper was: "To show that removal of the uterine appendages for myoma, when properly performed, is not a fatal operation, but one with hardly any mortality at all, even when the tumors are large, and when the patients are brought almost to death's door by hæmorrhage." In support of this proposition, he adduces fifty-eight operations, since January, 1884, without a single death. His entire modern experience gives a series of one hundred and eight cases, with two deaths, and he states his belief that the operation, in experienced hands, has a real mortality of not more than one per cent.

The second point: "That the results of the operation are satisfactory and permanent, so that we may with confidence recommend it for the relief of suffering and the saving of life," he endeavors to prove by a succinct summary of statements, relative to fifty cases, elicited from the practitioner who sent the case, his own personal observation, or the patient herself. Of the fifty cases, failure was observed in only two instances. One of these cases proved subsequently to be cancer of the body of the uterus. Menstruation was not arrested in the other case, and the tumor continued to grow. Two patients have been admitted to insane asylums, although in neither case could the operation be held accountable for the insanity.

Mr. Tait accordingly concludes that the statements, made in his paper on his first thirty cases, read May 24, 1881, before the Royal Medical and Chirurgical Society, and published in the *American Journal of the Medical Sciences*, January, 1882, have been abundantly sustained. Two of the conclusions in this paper have been substantially quoted. The third was: "That the whole subject was one well worthy of more study, and should not be made the subject of premature and hostile conclusions." It is seldom that one reads such a concise array of arguments, arranged in logical order, expressed in vigorous English, as constitutes Mr. Tait's paper. The essay reads like the demonstration of a theorem in Euclid. It is necessary, however, to bear in mind:

I. That the operation is usually difficult, sometimes impossible. Attention has been directed to this subject in an able editorial in the *British Medical Journal*, August 15, 1885.

II It is not always possible to remove all the ovarian tissue on both sides Unless this be done, the operation usually fails of its object

III After removal of the appendages, the patient must wait a long time for the subsidence of the tumor Sometimes the tumor remains unchanged, and exercises its untoward influences in the way of mechanical pressure, and a certain ill-defined pernicious constitutional effect

IV No living operator has approximated the success of Mr Lawson Tait

V A limited number of cases recover completely under judicious medication

VI In a certain proportion of cases, the tumor disappears spontaneously, or remains quiescent

VII Finally, after removal of all ovarian tissue, the tumor may continue to grow

THE BACTERIA OF SYPHILIS IN SMEGMA PREPUTII

During the past year Lustgarten has described a form of bacillus which he regards as pathogenic of syphilis It is about the size and in general appearance similar to the bacillus of tuberculosis He found it in the secretions from ulcers and in sections of hard chancre and mucus patches Lustgarten has also recommended methods of coloration which he believes to be absolutely characteristic

In the *Bulletin de l'Academie de Medecine*, for August 4, is a résumé, by Prof Cornil, of the work of MM ALVAREZ and TAVEL, who undertook, at his suggestion, a series of control observations upon those of Lustgarten, the results of which are of much interest They found a bacillus, in various normal secretions of the organism, which in form and color-reactions appears to be identical with Lustgarten's bacillus of syphilis They discovered the bacillus 33 times in 55 cases of hard chancre and other syphilides examined They found what appeared to be the same micro organisms in other non-syphilitic secretions from lesions of the genital organs, and also in many cases of smegma preputialis and vulveris It was rarely found except about the genital organs or edge of the anus, though it was sought for in the mouth, nose, ears, on the head, feet, and in folds of the skin, but unavailingly They suggest, therefore, that the bacillus of Lustgarten is this which they find in normal smegma, and that the microbes simply penetrate and become imbedded in syphilitic as well as other inflammatory tissues and secretions in the region of the genital organs

The bacillus observed by Alvarez and Tavel presents in form and many of its color reactions a strong resemblance to the bacillus of tuberculosis It can be distinguished from the bacillus of tuberculosis by its more slender proportions and less granular appearance If stained with methyl violet and decolorized with dilute nitric acid and washed with alcohol the bacilli are almost or quite completely decolorized If examined before washing in alcohol they appear slightly stained, showing that they do not well resist the decolorizing effects of alcohol Contrary to the observations of Lustgarten the microbe can be stained by Ehrlich's method with fuchsin, and resists the decolorizing powers of acid

The presence of this bacillus, and its very great similarity to the bacillus of tuberculosis, must be borne in mind by those examining urine, fecal matter and suspected tubercular lesions of the genital organs and anus, for the latter microbe A diagnosis can only be made by employing, with vigorous exactitude, the differential processes of coloration

MM Alvarez and Tavel have not as yet succeeded in cultivating the bacillus of smegma, and therefore have not been able to experiment upon its pathogenic powers

THE COMMITTEE ON ORGANIZATION OF THE NINTH INTERNATIONAL CONGRESS

The *Medical News* for August 29, under the head of The New Committee on the Organization of the Congress and the Old Committee," gives in parallel columns what it calls "the New Committee" and "the Original Committee" In the first column, headed "The New Committee," it gives correctly the names of the seven who constituted the Original Committee of Invitation, together with the one from each State and Territory, and from the Medical Corps of the Army, Navy, and Marine Hospital Service, making a total of forty seven members and fairly representing the Profession of the United States In the second column, however, under the head of "The Original Committee," it gives not only the names of the Original General Committee on the Organization of the Congress, but includes also the names of seventeen other parties, who constituted no part of said "Original Committee," having acquired only an *ex officio* or nominal membership through appointment to certain officials positions in the Congress

By this erroneous and deceptive method, the *Medical News* makes its column headed "The Original Committee" contain forty-two names, when no one knows better than the editor of the *News* that the Original Committee on the Organization of the Congress was composed of just twenty-five members, namely four from New York, three from Pennsylvania, three from the District of Columbia, two from Maryland, two from Massachusetts, two from Illinois, two from Georgia, and one each from Louisiana, Kentucky, Ohio, Missouri, South Carolina, California, and Canada Eight of the twenty-five constituted the primary Committee of Invitation, and the other seventeen were selected by the eight, by virtue of their power to increase the membership of the Committee It was this Committee of twenty-five that met in general session in Washington on the 29th of November, 1884, to adopt a plan of organization for the Congress Only fifteen of the twenty-five were present and took part in the meeting, and the General Committee as thus constituted was never convened again in general session Consequently the seventeen names of parties who had been assigned to prominent offices in the Congress, now added to the list to swell the number of members of the Committee to forty two, had no more to do with the work of the Original Committee on Organization than any other members of the profession

BACK NUMBERS OF THE JOURNAL —We have now received a sufficient number of the copies of the JOURNAL, for which we advertised in the issue of August 22, to supply our present need, and therefore withdraw the offer then made

SOCIETY PROCEEDINGS

AMERICAN DERMATOLOGICAL ASSOCIATION

Ninth Annual Meeting, held at Greenwich Connecticut, Aug 26, 27 *and* 28, 1885

WEDNESDAY, AUGUST 26—MORNING SESSION

The meeting was called to order at 10 o'clock by the PRESIDENT, DR W A HARDAWAY, of St Louis

DR J E GRAHAM, of Toronto, Canada, reported

A CASE OF TUBERCULO ULCERATIVE SYPHILIDE OF HEREDITARY ORIGIN

The patient was a girl 20 years of age On the right arm, from the wrist to the elbow, there was very little healthy skin, there being little but cicatricial tissue The skin of the forearm presents elevations and depressions, and in places it is covered with thin scales The head is not involved, and the affection does not extend deeper than the subcutaneous areolar tissue For three or four inches above the elbow, the arm is atrophied and covered with cicatricial tissue At the upper border of the cicatricial tissue, there is an ulcer three fourths of an inch wide, which encircles the arm Above this is sound tissue No nodules are present The left clavicle presents about its middle a swelling and ulceration about the size of a silver dollar This was the result of a blow There is no copper-colored appearance The heart and lungs are healthy and the urine normal Investigation of the family history showed that the mother was apparently healthy Three of the patient's sisters, all younger than herself, were healthy The father died from pneumonia when the patient was eighteen months old It was subsequently learned that he had also had syphilitic ulceration of the throat

The treatment consisted in the local application of a mild mercurial ointment, and the internal use of bichloride of mercury and iodide of potassium The condition steadily improved, and in the course of six or eight weeks the ulceration had healed The patient at that time passed from under observation

The speaker referred to the difficulties of diagnosis in this case, as there was a complete absence of specific history, the facts in regard to the father not being learned for some time after the case had been under treatment There was no history of any previous evidence of hereditary syphilis, but taking all the facts into consideration, the doctor thought there could be no doubt as to the correctness of the diagnosis Photographs showing the condition were exhibited

DR R W TAYLOR, of New York, thought that it is now generally conceded that syphilis can be communicated to the child without infection of the mother, and he believed that he was the first one in America to call attention to this fact He had seen this a number of times, and in cases where a most careful examination of the mother had been made, and the observations continued over a series of years The doctor had stated that he could obtain no history of early manifestations of hereditary syphilis This was not uncommon, but he believed that there is usually some indication of specific taint, which, however, may be so slight as not to excite notice, or its exact import is not recognized These may pass away, and in the course of six months or a year, the ulcerative lesions appear, but it is not uncommon for the child to go to the age of from six to eighteen years without exhibiting this condition

DR C HEITZMANN, of New York, thought that every one has seen cases similar to the one reported He had seen such cases in which he was unable to determine at first sight the nature of the affection The diagnosis lies between syphilis and scrofula

DR GREENOUGH, of New York, said that he would like to refer to the practical point to which Dr Taylor has called attention, and that was the possibility of the father infecting his progeny, without the mother showing any signs of syphilis Within the past two months he had seen a woman who had lost three children in succession from hereditary syphilis, yet she was strong and apparently perfectly healthy, and had never shown any signs of syphilis This woman had been under observation for six or seven years

DR L A DUHRING, of Philadelphia, thought that there are certain cases in which it was almost impossible to express a positive diagnosis at first The result of treatment in causing a rapid cure in the case described would certainly incline him to the opinion that this was a case of syphilitic disease

DR JAMES NEVINS HYDE, of Chicago, said that he had seen cases that convinced him that whilst it is not the rule, still, occasionally, syphilitic children are born where, so far as observation can be made, no evidence of syphilis in the mother can be detected As far as the general health is concerned, the women are usually pallid and weak, although there may be no symptoms which can be ascribed to syphilis He had never seen inherited syphilis manifesting itself in advanced years The more he saw of syphilis, the more he was satisfied that in its origin, heredity does not amount to very much The accidental cases of syphilis are very common He had seen the initial lesion of syphilis on the head of a penis where it was unquestionably due to inoculation from the finger of the surgeon in catheterization He had no doubt the case described was one of syphilitic trouble, and, as Dr Duhring had said, the result of treatment unquestionably points in that direction No cases yield so readily as old cases of untreated syphilis As to pronouncing it a case of hereditary syphilis, his experience would not permit him to do so

Dr W A Hardaway, of St Louis, thought that it is unwise to base diagnosis on the results of internal treatment Because a case gets well under antisyphilitic treatment is not proof that the affection is specific in its nature Local treatment is often all that is necessary

Dr R W Taylor said that Dr Hyde had made the statement that these women apparently unsyphilitic who have borne syphilitic children, have in his experience been pallid and weak He entirely disagreed with him on that point

Dr F B Greenough, of New York, then read some

CLINICAL NOTES ON PSORIASIS

The paper was founded on the records of 394 cases of psoriasis This number occurred in about 15,000 cases of skin disease examined, and represented about two and one-half per cent , 205 cases occurred in males and 188 in females Several tables of statistics were presented, showing when the cases first came under observation and the age at which the attack was first observed A large proportion of the cases was first attacked with psoriasis between the ages of ten and forty years, but the fact that one-seventh of the cases showed psoriasis before the age of seven years was not in accordance with previous observations In 97 cases the speaker had been able to get reliable evidence in regard to the family history In 31 cases psoriasis had existed in a near relative, but in 66 cases the patients felt sure that the disease had existed in no other member of the family

As regards locality affected, where there is much development, it is almost constantly found about the elbows and knees, and more frequently on the extensor surfaces than on the flexor There is one class of cases where the affection attacks only the skin of the leg below the knee Well marked cases are readily diagnosticated, but in some cases there is considerable difficulty in making the diagnosis It is most frequently confounded with some form of eruption resulting from constitutional syphilis When psoriasis affects the scalp, its appearance is often similar to that of secondary syphilis In psoriasis, however, the patch consists simply in epithelial cells and there is no hyperæmia connected with it In syphilitic eruption, the crust will contain other elements than epithelial cells, and on removal of the crust spots of moisture will be detected A characteristic symptom of psoriasis of the scalp is a band of hyperæmia, about three fourths of an inch wide, extending around the forehead, contiguous to the hair This is a point of value in the diagnosis between eczema capitis and psoriasis In the former affection this band is wanting In eczema, also, evidences of dried serum or pus will be found Psoriasis is not accompanied with enlargement of the post-cervical glands, as is eczema The diagnosis from favus is made by the age of the patient The evidences of the destruction of the hair follicles in Favus and the microscopical examination He had never been able to satisfy himself that psoriasis of the scalp ever caused permanent loss of the hair

On the general integument, syphilides are most apt to resemble psoriasis The regions on which the eruptions appear is important The syphilides are apt to affect the flexor surfaces, while the psoriasis affects more commonly the extensor aspects Psoriasis begins as a minute point of hyperæmia, which may last for several days In macular syphilide a crop of macules appear within twenty four or forty eight hours, when the eruption fades There is in syphilis a decided pigmentary change In squamous syphilis the epithelial scales differ from those of psoriasis In some cases of psoriasis there is severe itching, leading to scratching of the skin, and as a result scabs and crusts make their appearance, but here the cause of the condition is readily recognized The amount of pruritis complained of in psoriasis varies, but it is rarely a prominent symptom, although in exceptional cases it is very severe He has never seen any eruptions on the hands or feet resembling psoriasis, with the exception of eczema, which was not syphilitic

In regard to treatment, some cases do well, while others do not There is no specific What will benefit one case will make another worse In his experience tary preparations, especially the oil of cade, have been most efficacious Great comfort may be afforded by the use of emolients Cod-liver oil is one of the best applications Cod-liver oil and the oil of cade (equal parts) is a common prescription Chrysarobin is a powerful remedy, but has the disadvantage of destroying the clothing On the face and scalp it is apt to produce dermatitis The internal administration of arsenic in some cases is of benefit Even after apparent recovery, there is great danger of relapse

Dr L A Duhring said that the reader of the paper, in referring to the diagnosis, did not allude to the difficulty sometimes experienced in diagnosing seborrhœa capitis from psoriasis He had found considerable trouble in the diagnosis, particularly in young girls In these cases the eruption was confined to the scalp

Dr A R Robinson said that in regard to the diagnosis of favus and psoriasis, there is usually no difficulty He did not agree with the author in regard to one of his points of diagnosis In the early stage you do not find moisture when the crust is removed There is a shiny appearance It is only in advanced stages that ulceration is present He agreed with the speaker that psoriasis always occurs in small spots at first not covered with scales While it is true that psoriasis often disappears without producing pigmentation, yet there may be discoloration found on the lower extremities, particularly where there is a varicose condition of the veins In some cases where there are only a few patches of psoriasis, limited to the lower extremities, it is often difficult to make the diagnosis, unless there is involvement of other parts of the body, or you have the history There are other cases of acute psoriasis which closely resemble acute eczema In reference to the palms of the hands, whilst we do not see cases of psoriasis limited to this condition, yet he was sure that cases have been shown in which the palms of the hands have been affected in connection with other portions of the body

DR J C WHITE, of Boston, agreed with the previous speakers in regard to the difficulty of diagnosing between psoriasis of the scalp and seborrhœa In some cases the diagnosis can not be made for months In all parts of the body pigmentation may follow psoriasis, but never over large areas He called attention to one termination which he had seen in three cases, and that was a degeneration into epithelioma

DR R B MORRISON, of Baltimore, had seen a great many cases of psoriasis, but could recall only one or two cases of psoriasis in the negro In such cases, there is a loss of pigment

DR G H FOX, of New York, thought that too much stress was laid on the general rule that psoriasis occurs most frequently on the extensor surfaces, the knees and the elbows It is a notable fact that in general psoriasis, the vicinity of the knee and elbow escapes Many cases of psoriasis occur in weakly subjects, while on the other hand, many cases of eczema appear in robust persons In every individual case, the better the patient's health, the less likely is he to suffer from a recurrence of the affection He had been very successful in the treatment of psoriasis, and in its management He adopted the teaching of the late Tilbury Fox, who laid stress on the point that in psoriasis, as in other inflammatory affections of the skin, and also in lupus, the first thing to do is to lessen the congestion of the skin He did this by restricting the diet He cuts off the meat and orders a diet of fruits and vegetables in the summer, and in the winter gives a carefully restricted diet Tea, coffee, tobacco, and stimulants of all kinds are to be cut off By so doing more will be accomplished than is obtained by using arsenic and local applications at the start

In regard to local remedies he never uses tar in the treatment of psoriasis With the application of chrysarobin made at the proper time, there is no necessity for the use of tar He had seen many cases in which this drug did no good, but this was because the application was made when the patches of psoriasis were in a congested condition If the acute congestion is lessened, chrysarobin will produce beneficial results

DR C HEITZMANN thought that one of the most important points after making the diagnosis is to decide as to the acuteness or chronicity of the affection If it is acute, local applications are to be avoided If the case is chronic chrysarobin may be used with advantage, at least temporarily It is not a cure He agreed with Dr Fox that restriction of the diet is important for the purpose of lessening the congestion Tar can not be dispensed with Chrysarobin remedies the disease for a time, but in a few months it returns There is nothing like tar to prevent the recurrence No mention had been made of pyro gallic acid, which does good in some cases There are, however, some cases which can not be treated successfully with any remedies The disease will steadily grow worse

DR W A HARDAWAY believed that in psoriasis we have a disease situated in the skin itself It is frequently hereditary The same sort of skin may be transmitted just as a certain color of the hair or of eye may be transmitted, and then any exciting cause may develop the psoriasis Traumatism is frequently the exciting cause He had seen psoriasis follow eczema It is not unlikely that in seborrhœa of the scalp there may be the development of psoriasis Internal causes may produce it He had seen the excessive use of oat meal produce typical psoriasis

In the treatment of psoriasis it is important to regulate the diet and aid digestion in all possible ways As a local application, he considered that chrysarobin, with salicylic acid, was very useful in chronic cases Arsenic is useful on account of its action on the skin This treatment may be followed up by the application of sulphur ointment In psoriasis of the scalp sulphur is quite an efficient remedy

DR GREENOUGH said he had not intended to cover the entire ground of psoriasis in his paper The omission of a consideration of seborrhœa was an oversight In regard to pigmentation, he referred especially to those cases of psoriasis of the trunk, which were most apt to be confounded with syphilides

DR J C WHITE, of Boston, then reported some

CASES OF ANGIOMA PIGMENTOSUM ET ATROPHICUM

Two cases were reported The first patient was a young man 17 years of age, and a Russian Pole by birth Freckles appeared on his face before he was 2 years of age These increased in number until the age of 6 When the telangiectasic condition first appeared is not noted When seen, the patient was well developed and apparently *in good health* He has, however, grown slowly, and is now no larger than a boy of 12 The hair of the head is abundant and intensely black The eyes are also black

Present Condition —Melanosis The forehead and lower portion of the face are of a dark brown color, and on close inspection, small spots of a darker color are seen The whole trunk is as dark as the skin of a dark Spaniard The scrotum is very black, and the penis and glans present dark spots The arms and hands are thickly spattered The legs are also affected On the right thigh there is one spot of dark color, covered with rather long hair The mucous membrane of the mouth and pharynx is free from melanosis

The Atrophic Condition —On the right side of the face occupying one half the surface is a sharply defined area of white cicatricial looking skin Similar areas are seen on the other cheek, forehead and about the mouth A few white spots are seen on other portions of the body The sensibility of the affected areas is decidedly lessened

Telangiectasis —Over parts of the face, there are bright red spots, varying in size from a pin's head to a pea They are most noticeable in the atrophied portions Within the lids, there are two angiomatous new growths Several vascular twigs are also seen on the face A few red points are found on the feneral surface

The second case is a brother of case 1, aged three years, born in New York When 18 months old, little colored freckles were noticed on the face Since then the condition has been developing His hair is dark brown and eyes are black The face is covered with numerous dark brown freckles The spots are so close together that at a little distance, the skin has a uniform color In some places, the spots are slightly elevated The backs of the hands are covered with dark-brown spots, elsewhere the skin is clear There are no leucodermic spots and no angiomatous condition

From a study of these cases, he concluded that in the beginning, the development of these spots can not be distinguished from ordinary freckles Gradually they multiply until they involve a considerable portion of the skin It is probably, that several years may advance without other manifestation of the disease The telengiectasic condition is probably secondary In the first case it is most developed in the atrophic portion It is probable that in this case, there will be hypertrophy of the epithelium and final transformation into epithelioma This has been the result in the thirty-three cases which have been reported

DR TAYLOR thought that there was a direct relation between the red spots and the macules The history of the cases which he had seen, had been first a rash, then the red spots, and then the macules In one case, the telemectasis followed exposure to heat

DR WHITE recognised a great difference in this disease as described by various writers, but he insisted on the correctness of his own observation The younger child had exhibited none of the precedent hyperæmia which has been noted in some cases The patient has been observed after exertion and when exposed to intense heat, but there has been no hyperæmia The same is true of the first case as far as known In the second case which is still developing, there is no enlargement of the vessels

(*To be concluded*)

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Passage of Pathogenic Microbes from the Mother to Fœtus The Couveuse—Experiments after Decapitation Duration of the Excitability of the Brain—The Death of Milne Edwards

M Koubassoff lately made a very interesting communication at the Academy of Sciences relative to the passage of pathogenic microbes from the mother to the fœtus and of the passage of the parasite of charbon in particular, which has a real practical importance as regards the preservative action of charbon inoculation The following is a summary of M Koubassoff's note on the subject 1 The bacilli of charbon always pass from the mother to the fœtus, 2 The longer the duration of time that elapses between the inoculation of the pregnant female and her death, the more numerous will be the microbes in the fœtus, 3 A greater number of virulent bacilli of charbon than those of the attenuated kind always passes from the mother to the fœtus, 4 The pathological condition of the membranes of the placenta and of the fœtus, as well as the death of the latter, prevent the passage of the bacilli from the mother to the fœtus, 5 The inoculation of pregnant females with too strong vaccine material causes almost always the death of the fœtus, 6 The inoculation with cultivated material of a pregnant female, who has already been inoculated, almost always kills the fœtus—those who survive after the inoculation with cultivated material are those that have not been sufficiently vaccinated by the mother

In a former letter I gave an account of a cradle adopted at the Paris Maternity for the use of new-born infants of feeble constitutions, and particularly for those of premature birth, to which the name of "couveuse" was given This brought up the reduced temperature of the infants to about the normal (37° C), and, by a simple arrangement, maintained it at that degree Professor Tarnier, surgeon-accoucheur at the Maternity has now introduced a system of feeding such infants with milk passed through an india-rubber catheter (No 16 of the French scale), one end of which is introduced into the stomach, and to the other end is adapted a small glass funnel, through which is passed from three to fifteen grammes of milk, that of a woman being preferred As soon as the milk enters the stomach the catheter should be removed without delay, as otherwise vomiting may be provoked, which, of course, would render the operation useless The "gavage," as this mode of feeding is termed in French, should be repeated every hour, and continued until the infant is strong enough to suck for itself Professor Tarnier is convinced that infants born before the seventh month, and even those of the sixth month, could be brought up in this way At this meeting of the Academy M Tarnier presented two infants whose lives were saved by this method The first was one of twins It weighed 1,020 grammes at its birth, and the mother stated that the date of conception could scarcely extend beyond six months The weight of the infant, a short time after its birth, fell to 950 grammes, but under the influence of this artificial feeding it soon mounted up to 1,015 grammes Twenty days after its birth the child was able to take the breast Its twin brother, born with a weight of 1,120 grammes—that is to say, with a superior weight—did not survive The second infant that was presented was seen by M Tarnier only three days after its birth , its weight, which was 1,100 grammes, descended to 1,000 grammes, but under the influence of the gavage it rose gradually, and at the date of its presentation, it was scarcely a month old, it weighed 1,500 grammes This method of feeding infants of weak constitutions whatever be the cause, and if unable to take the breast, would, M Tarnier thinks, be the means of saving many a life, and he added in his note on the subject that the couveuse would be an indispensable complement to the above method in such circumstances, for he has seen infants affected with sclerema, appearing to be doomed to imminent death, recover in twenty-four or thirty-six hours

With reference to the experiments that were performed on the head of a man guillotined at Troyes and to those that were performed previously under the same circumstances, M Paul Bert made the fol-remarks at a recent meeting of the Societé de Biologie of Paris In a general way it appeared to him that such experiments were of little or no value, and those who performed them exposed themselves to a great moral responsibility The objects in view in performing these experiments may be divided into two categories—the one, to study on the decapitated man the mechanism of a certain number of phenomena of the circulation, of secretion, etc These results may be obtained by practising on animals, and in ten times better conditions In the other groups of experiments it is proposed to determine whether, after decapitation, intelligence persists, or whether it has disappeared, and, in the latter case, whether it is possible to make it reappear It is now generally admitted that after decapitation consciousness is abolished, and even admitting that, by means of the artificial injection of blood, it may appear to be re-established, which, however, is only a hypothesis, yet M Bert thinks one has no right to try such an experiment, as he compares it to torture post mortem

This debate was renewed at a subsequent meeting of the Academy of Sciences, in which Professor Vulpian took part This learned physiologist quite agreed with M Paul Bert, and added that to perform such experiments was to follow a chimera, as they never give any results worth having Hence it would be inexcusable in any person moved by scientific passion to continue such practices

At the same meeting Professor Vulpian gave an account of some experiments he had performed to ascertain the duration of the excitability of the brain after death In exposing the brain of a dog at the moment of its death it is noticed that the cerebral substance is still excitable during a period varying from forty five to sixty seconds, that is to say that, under the influence of Faradic excitation of one side of the brain, movements are still produced on the opposite side which extend to the extremities and then to the face When this time is passed, the Faradic excitations, even the strongest, do not determine the least muscular quivering of the opposite side These experiments were performed on an adult dog, but it is probable that the results would be identical in other mammifers, except in hibernating animals in a state of hibernation

M Milne-Edwards, the celebrated naturalist, whose health had been declining for some time, died on the 28th inst , in the 86th year of his age He took his degree of Doctor of Medicine of the Faculty of Paris in 1823 After some years he devoted himself entirely to the study of the natural sciences He was for many years Dean of the Academy of Sciences, and Member of the Academy of Medicine He was Grand Officier of the Legion of Honor, and member of several learned societies in France and other countries A B

(FROM OUR OWN CORRESPONDENT)

The Use of Alcohol in Sickness—Over Pressure in Schools—The Congress of Teachers of the Blind—Cholera Beds at St Bartholomew's Hospital—Deodorization of Sewers—How to Bring up Babies—The Gordon Memorial Hospital

At least two interesting papers were read at the meeting of the British Medical Association at Cardiff Dr Norman Kerr's subject was "Ought we to Prescribe Alcohol?" and his moderate and sensible remarks may be recommended to the consideration of every physician There were medical men (said Dr Kerr) who seemed to order wine and spirits for patients of both sexes, and at all ages, in every ailment There were, again, daring innovators who denied that alcohol in any form or in any quantity possesses useful medicinal virtues Medical men ought to limit their prescription of alcohol to the occasion, taking care that the medicine was not continued after the purpose for which the stimulant was given had been gained This pretty fairly sums up the whole question There is small doubt, on the one hand, that many people, especially ladies, have been led into habits of secret drinking by the insidious advice of accommodating medical men, and on the other hand, it is idle to deny that, under some circumstances, wine and spirits are not only useful, but necessary medicines The difficulty is how to prescribe alcohol in moderation without encouraging its use after the necessity has passed, and if Dr Norman Kerr succeeds in showing how to avoid this dilemma, he will have deserved well

The other paper, that of Dr I Martin on "Over-Pressure in Schools," ought to prove instructive to educational fanatics Over-pressure, according to Dr Martin, injures health and produces misery, both for parents and children "Children had to pore over their lessons until ten, eleven, and twelve o'clock at night Next morning the child could not eat its breakfast, and then followed headaches, vomiting, nervous debility, brain fever, St. Vitus' dance, curvature of the spine, heart disease, myopia, and in some cases convulsions and death." Dr. Martin went on to quote the authority of Professor Pfluger for the statement that, of 45,000 children examined in Germany, half suffered from defective vision, and from 30 to 40 per cent. of the girls from curvature of the spine.

At the opening of the Congress of Teachers of the Blind at Amsterdam, nearly 200 members from all parts of Europe were present. The President, Herr Meyer, from the Amsterdam Institute, announced that the Queen of Holland had consented to become the patron of the Congress. The Home Minister was present at the first sitting. The leading feature of the day was an address by Dr. Armitage, of London, upon American institutions for the blind. An exhibition of the works of the blind has been opened in the University buildings.

At St. Bartholomew's Hospital, forty beds have been kept ready for the reception of any cases of cholera that may be brought to the doors, should that disease unfortunately visit our shores, and an entire wing, containing nearly two hundred beds, could at a very short notice be prepared for the reception of similar cases. This wing, isolated from other wings, would be nursed by a separate staff of skilled nurses. Dr. Norman Moore having been appointed Resident Physician, responsible for the reception and immediate treatment of cases, has given up his summer holiday in order that he may be continuously on duty in the event of his services being required. At Plymouth, also, active precautions are being adopted. An old man of war has been moored in the Sound, and the local authorities are making arrangements to transfer there immediately all suspected cases.

The Metropolitan Board of Works have this summer taken effective measures to deodorize the outfalls and main sewers. They are now pouring into the sewers of the metropolis and at the outfalls between thirty and forty tons of manganate of soda, and from ten to twelve tons of sulphuric acid every day, and are spending between £3,000 and £4,000 a week in thus deodorizing the sewers and outfalls. The result of this work has been that the condition of the Thames might be said to be good. There are perhaps sections of discolored water, but they are offensive only to the eye, and not offensive to the smell.

The town council of Exeter have just issued a circular, which has been sent round to the women of the city, instructing them "how to bring up babies." The council, it appears, have been alarmed by the large amount of infant mortality in the city. They have therefore conferred, and the result is that they call upon the women of Exeter to keep their babies warm, to give them nightgowns with long sleeves, and to wash them all over every day. Two months babies must have milk from the breast once in two or three hours, and a six months child five times in twenty-four hours. The baby should be weaned when seven months old. The bottles, it is added, should draw easily and be kept well rinsed.

As the authorities have been unable to decide upon a suitable site on the Suez Canal for the erection of the proposed Memorial Hospital to the late General Gordon, the hospital at Port Said has been materially improved, and latrines will be erected as soon as it is determined whether the dry earth system or the pneumatic cart should be adopted. G. O. M.

DOMESTIC CORRESPONDENCE.

AN OPEN LETTER TO THE EDITOR OF THE MEDICAL NEWS, OF PHILADELPHIA, PA.

Dear Sir:—As a subscriber to your journal, and as one who is wedded to the medical profession by more than fifty years of unceasing devotion to its high behests, I may justly claim the privilege, if not the right to address you, who have hitherto been acknowledged as one of the honored exponents of medicine and an able defender of its unimpeachable *Code of Ethics* as set forth in the Constitution and By-Laws of the American Medical Association. And I claim that I can with propriety address you, since as delegate to the American Medical Association, at its late session in New Orleans, from the Louisiana State Medical Society, I did not approve in its entirety the action of that body towards the Original Committee appointed at the Washington meeting in 1884, to invite, in the name of the medical profession of the United States, the meeting of the next International Medical Congress in this country, and to make all suitable arrangements for its meeting, if the invitation was accepted.

While I believe, and affirm, that the Original Committee erred and acted unwisely, and in opposition to the enlightened judgment of a vast majority of the medical profession of the United States, in whose name the invitation had been extended, and in direct conflict with the honor and integrity and dignity of the American Medical Association, in selecting and appointing to posts of honor men notoriously antagonizing and setting at naught the Code of Principles and Ethics unanimously adopted, and cherished by our best men as cardinal and sacred, binding together all true men in the profession, yet as the Committee acted in good faith, and, as they believed, for the best interests of the profession, I thought their action ought to be courteously endorsed and supplemented by a vigorous and cheerful support. But a majority of the delegates thought differently and deemed it best to add to the Original Committee other members, from all the States and Territories, to make the work more national and unsectional, and more truly to represent the medical profession of the United States in the International Medical Congress, to meet in Washington City in 1887.

Words cannot express the pain and mortification which your course, and language in the *Medical News*, have given me in relation to this subject. Instead of counseling harmony and mutual concessions in the interest of peace and the preservation of the integrity and honor of the medical profession, you have seemed to take pleasure in magnifying the diftion could scarcely extend beyond six months The weight of the infant, a short time after its birth, fell to 950 grammes, but under the influence of this artificial feeding it soon mounted up to 1,015 grammes Twenty days after its birth the child was able to take the breast Its twin brother, born with a weight of 1,120 grammes—that is to say, with a superior weight—did not survive The second infant that was presented was seen by M Tarnier only three days after its birth, its weight, which was 1,100 grammes, descended to 1,000 grammes, but under the influence of the gavage it rose gradually, and at the date of its presentation, it was scarcely a month old, it weighed 1,500 grammes This method of feeding infants of weak constitutions whatever be the cause, and if unable to take the breast, would, M Tarnier thinks, be the means of saving many a life, and he added in his note on the subject that the couveuse would be an indispensable complement to the above method in such circumstances, for he has seen infants affected with sclerema, appearing to be doomed to imminent death, recover in twenty-four or thirty-six hours

With reference to the experiments that were performed on the head of a man guillotined at Troyes, and to those that were performed previously under the same circumstances, M Paul Bert made the fol remarks at a recent meeting of the Societe de Biologie of Paris In a general way it appeared to him that such experiments were of little or no value, and those who performed them exposed themselves to a great moral responsibility The objects in view in performing these experiments may be divided into two categories—the one, to study on the decapitated man the mechanism of a certain number of phenomena of the circulation, of secretion, etc These results may be obtained by practising on animals, and in ten times better conditions In the other groups of experiments it is proposed to determine whether, after decapitation, intelligence persists, or whether it has disappeared, and, in the latter case, whether it is possible to make it reappear It is now generally admitted that after decapitation consciousness is abolished, and even admitting that, by means of the artificial injection of blood, it may appear to be re'established, which, however, is only a hypothesis, yet M Bert thinks one has no right to try such an experiment, as he compares it to torture post-mortem

This debate was renewed at a subsequent meeting of the Academy of Sciences, in which Professor Vulpian took part This learned physiologist quite agreed with M Paul Bert, and added that to perform such experiments was to follow a chimera, as they never give any results worth having Hence it would be inexcusable in any person moved by scientific passion to continue such practices

At the same meeting Professor Vulpian gave an account of some experiments he had performed to ascertain the duration of the excitability of the brain after death In exposing the brain of a dog at the moment of its death it is noticed that the cerebral substance is still excitable during a period varying from forty five to sixty seconds, that is to say that, under the influence of Faradic excitation of one side of the brain, movements are still produced on the opposite side which extend to the extremities and then to the face When this time is passed, the Faradic excitations, even the strongest, do not determine the least muscular quivering of the opposite side These experiments were performed on an adult dog, but it is probable that the results would be identical in other mammifers, except in hibernating animals in a state of hibernation

M Milne-Edwards, the celebrated naturalist, whose health had been declining for some time, died on the 28th inst, in the 86th year of his age He took his degree of Doctor of Medicine of the Faculty of Paris in 1823 After some years he devoted himself entirely to the study of the natural sciences He was for many years Dean of the Academy of Sciences, and Member of the Academy of Medicine He was Grand Officier of the Legion of Honor, and member of several learned societies in France and other countries A B

DOMESTIC CORRESPONDENCE

AN OPEN LETTER TO THE EDITOR OF THE MEDICAL NEWS, OF PHILADELPHIA, PA

Dear Sir —As a subscriber to your journal, and as one who is wedded to the medical profession by more than fifty years of unceasing devotion to its high behests, I may justly claim the privilege, if not the right to address you, who have hitherto been acknowledged as one of the honored exponents of medicine and an able defender of its unimpeachable *Code of Ethics* as set forth in the Constitution and By Laws of the American Medical Association And I claim that I can with propriety address you, since as delegate to the American Medical Association, at its late session in New Orleans, from the Louisiana State Medical Society, I did not approve in its entirety the action of that body towards the Original Committee appointed at the Washington meeting in 1884, to invite, in the name of the medical profession of the United States, the meeting of the next International Medical Congress in this country, and to make all suitable arrangements for its meeting, if the invitation was accepted

While I believe, and affirm, that the Original Committee erred and acted unwisely and in opposition to the enlightened judgment of a vast majority of the medical profession of the United States, in whose name the invitation had been extended, and in direct conflict with the honor and integrity and dignity of the American Medical Association, in selecting and appointing to posts of honor men notoriously antagonizing and setting at naught the Code of Principles and Ethics unanimously adopted, and cherished by our best men as cardinal and sacred, binding together all true men in the profession, yet as the Committee acted in good faith, and, as they believed, for the best interests of the profession, I thought their action ought to be courteously endorsed and supplemented by a vigorous and cheerful support But a majority of the delegates thought differently and deemed it best to add to the Original Committee other members, from all the States and Territories, to make the work more national and unsectional, and more truly to represent the medical profession of the United States in the International Medical Congress, to meet in Washington City in 1887

Words cannot express the pain and mortification which your course, and language in the *Medical News*, have given me in relation to this subject Instead of counseling harmony and mutual concessions in the interest of peace and the preservation of the integrity and honor of the medical profession, you have seemed to take pleasure in magnifying the differences of opinion, in stirring up strife and sowing dissensions and even hatreds between members of the medical profession That one, who heretofore has so nobly defended the Code of Ethics and the honor and integrity of the American Medical Association against the few agitators in New York who presumptuously imagine that they constitute the head and body of the entire medical profession of this country, and arrogantly set themselves up as above the American Medical Association, that you, its former friend and supporter, should in this the first trying hour of its nationality and authority, turn against her as you have done, is humiliating to the medical profession and mortifying to your readers

You very erroneously, I think, assert in the *Medical News* that the American Medical Association does not represent the medical profession of the United States Pray, sir, with all due deference, if the American Medical Association does not represent the medical profession of the United States, what medical organization does?

You are equally mistaken when you presume to claim that the few learned and scientific men in Philadelphia, New York, Boston, Baltimore, and Washington City, who are antagonizing the authority and action of the American Medical Association, are superior, in point of intelligence and scientific medical knowledge, to those who will not surrender their honor, but manfully and nobly sustain our national medical organization And let me assure you, that the few who are rendering themselves ignobly conspicuous in trying to obstruct the action of our National Association, are not the real leaders of American thought and opinion in this country, as you seem to think they are, and as they claim for themselves But you may, by distortion of facts and misrepresentation of honest differences of opinion, succeed in defeating the successful meeting of the contemplated International Medical Congress in this country in 1887, and you may disintegrate and disrupt the American Medical Association, but if so, what will you have gained? What will be your reward but remorse and chagrin? My dear sir, think of the consequences, retrace your steps, recall your words of evil import before it is too late, and use your talent and acknowledged ability in counselling peace and harmony in the profession, by mutual and honorable concessions on the part of each side "*Blessed are the peace-makers*" Respectfully,

RICHARD H DAY

Baton Rouge, La , August 22, 1885

THE ORIGINAL COMMITTEE ON ORGANIZATION OF THE INTERNATIONAL CONGRESS

TO THE EDITOR OF THE JOURNAL

Dear Sir —Sir James Paget's letter on the subject of the International Congress, is a wonderful example of the fulfilment of a prophecy of what he would write, made some time since by one of the self-elect How far Sir James was inspired, the privacy of the mail prevents our knowing, but for his benefit and that of the various foreign journals which are being brought into service at this time with surprising simultaneity, the following facts are here set forth, to which not one of them have yet referred

I That the Committee of Seven (afterwards eight) who were appointed *by the American Medical Association* to invite the Congress to the United States, and to make a preliminary organization, were

1 Austin Flint, Sr , of New York
2 I Minis Hays, of Philadelphia
3 J S Billings, of U S Army
4 J M Browne, of U S Navy
5 C Johnston, of Baltimore
6 L A Sayre, of New York
7 G J Engelmann, of St Louis
8 H F Campbell, of Augusta

II That the principal officers selected for the Congress *by these seven* (eight) were

1 Austin Flint, Sr , *President, and Member of Executive Committee*
2 I Minis Hays, *Chairman of Executive Committee*
3 J S Billings, *Secretary-General, and Member of Executive Committee*
4 J M Browne, *Treasurer, and Member of Executive Committee*
5 C Johnston, *Member of Executive Committee*

This constituted a *majority* of the Executive Committee, which is all anybody wants in an executive body The others were, however, not wholly unprovided for

6 G J Engelmann, *Secretary of the Section of Gynecology*
7 H F Campbell, *Vice-President of the Congress*

Perhaps Sir James Paget will favor us with some deductions from the premises, and oblige A M A

BOOK REVIEWS

THE TECHNOLOGY OF BACTERIA INVESTIGATION EXPLICIT DIRECTIONS FOR THE STUDY OF BACTERIA, ETC By CHARLES S DOLBY, M D Published by S E Casino & Co , Boston Chicago Jansen, McClurg & Co

This work is intended to give quite exhaustively the methods used by various observers in the study of bacteria In the first part, entitled "General Directions," the different methods which have been employed for studying bacteria in air, water, living organisms, and preserved or hardened specimens, are described Special methods of preparation for photographic purposes are also considered, as well as the various forms of culture experiments, vaccination and inoculation experiments, and the general biological phenomena of bacteria The second part is devoted to descriptions of the methods that have been used for finding and studying the special microbes of the different diseases Twenty-five such diseases are considered, and when more than one form of microbe has been found and thought pathogenic by different observers, each has been described Part third is devoted to formulæ of the various staining and other reagents, and culture media

The book will therefore be seen to be quite exhaustive in its description of methods of study. Little or no space is devoted to a discussion of the true pathogenic nature of the various microbes, but all is given to a consideration of the technology of the study. The book will, therefore, be found particularly valuable to those who wish to study bacteria practically in the laboratory. The author, in the preface, expresses the wish that it may stimulate such work in this country, a wish in which we heartily unite with him.

A particularly valuable feature of the book is the very full enumeration of the works constituting the literature, which is appended to each subject.

ASSOCIATION ITEMS.

MEMBERSHIP BY APPLICATION.

At the meeting of the American Medical Association held at Washington, in May, 1884, an amendment to Regulation II was adopted, which provides that membership in the Association shall be obtainable by any member of a State or County Medical Society recognized by the Association, upon application endorsed by the President and Secretary of said Society, and shall be retained so long as he shall remain in good standing in his local Society, and shall pay his annual dues to the Association. Hitherto attendance as a delegate at an annual meeting has been necessary in order to obtain such membership.

Application for membership, accompanied with Five Dollars, for annual dues, and the Certificate of Membership in the local Society, should be sent directly to the undersigned, on receipt of which the weekly Journal of the Association will be forwarded for one year.

Richard J. Dunglison, M.D., *Treasurer*,
Lock Box 1274, Philadelphia, Pa.

MISCELLANEOUS.

MEDICAL SOCIETY OF VIRGINIA—SIXTEENTH ANNUAL SESSION.

The Medical Society of Virginia will convene at Alleghany Springs, Montgomery County, Va., at 7.30 o'clock, Tuesday night, September 15, 1885. Alleghany Springs is about four miles from Shawsville, on the Norfolk and Western Railroad, twenty-three miles west of Roanoke, and seventy seven miles west of Lynchburg. Shawsville is the station for which all railroad passengers must secure their tickets.

The Address of Welcome will be delivered by Dr. Isaac White, Physician to the Springs, and the Report of the Committee to Nominate Applicants for Fellowship will be presented and acted on. Dr. H. M. Clarkson, of Hay Market, Va., will then deliver the Address to the Public and Profession. The President, Dr. Samuel K. Jackson, of Norfolk, will then deliver the President's Address. Dr. Isaac White, of Shawsville, Va., will read a paper on the Medical Virtues of the Alleghany Springs Water, Va. Any business of a general character may next be transacted, and announcements of programme, etc., will be made before adjournment. On Wednesday morning, the Society will be called to order at 10 o'clock. After the usual form of opening the meeting, the Reports of the Secretaries, the Treasurer, the Committee on Publications, the Executive Committee, the Necrological Committee, the Committee appointed in 1884 to confer with the professions of Virginia, West Virginia and North Carolina with reference to the organization of a Tri-State Medical Association (Dr. Joseph A. White, Richmond, Chairman), and the Report from the State Board of Medical Examiners, will be severally called for and disposed of. New business may be then introduced.

The subject for general discussion—Scarlet Fever—will be taken up at 11.30 A.M., Dr. Thomas J. Moore, Richmond, Va., leader. After Dr. Moore will have opened the discussion, other Fellows and delegates will be entitled to the floor for remarks in the order in which they may be recognized by the Chair. It is expected that those who enter into the discussion will prepare their papers beforehand, or else, immediately after the discussion, will furnish notes of what they may have said to the Secretary, in order that the remarks may be correctly entered on the records of the session, and thus prove of lasting value to the Society. If any time remains after the discussions till dinner hour, it may be occupied by new business, motions, communications, etc.

The Afternoon Session will be devoted to the election of officers and annual committees, including the Necrological Committee for the succeeding term, and of the Fellow to deliver the Address to the Public and Profession in 1886. The election of Honorary Fellows will also be in order, as also the selection of the subject for general discussion, 1886, and the leader in the discussion. The place of meeting of the Seventeenth Annual Session is also to be selected.

The Night Session will open with the call for Reports on Advances in the several departments of medical sciences, and the following order will be observed until adjournment to Thursday morning, when the call will be continued until the order is completed:

1. *Report on Anatomy and Physiology*, by Dr. J. O. Jones, of Harrisonburg.

2. *Report on Chemistry, Pharmacy, Materia Medica and Therapeutics*, by Dr. M. G. Ellzey, Washington, D. C.

3. *Report on Obstetrics and Diseases of Women and Children*, by Dr. S. W. Dickinson, Marion, Va. In this section the following papers will be presented: (*a*) Successful Treatment of Lacerations of the Os Uteri, without Surgical Operation. By Dr. Bedford Brown, Alexandria, Va. (*b*) Puerperal Septicæmia, especially with Regard to Prophylaxis and Etiology. By Honorary Fellow Dr. George T. Harrison, New York, N. Y. (*c*) Infanticide. By Dr. Chas. R. Cullen, Henrico Co., Va.

4. *Report on Surgery*, by Dr. H. Grey Latham, Lynchburg, Va. In this section the following paper will be presented: (*a*) Treatment of Hip Joint Disease. By Dr. Lewis Wheat, Richmond, Va.

ferences of opinion, in stirring up strife and sowing dissensions and even hatreds between members of the medical profession That one, who heretofore has so nobly defended the Code of Ethics and the honor and integrity of the American Medical Association against the few agitators in New York who presumptuously imagine that they constitute the head and body of the entire medical profession of this country, and arrogantly set themselves up as above the American Medical Association, that you, its former friend and supporter, should in this the first trying hour of its nationality and authority, turn against her as you have done, is humiliating to the medical profession and mortifying to your readers

You very erroneously, I think, assert in the *Medical News* that the American Medical Association does not represent the medical profession of the United States Pray, sir, with all due deference, if the American Medical Association does not represent the medical profession of the United States, what medical organization does?

You are equally mistaken when you presume to claim that the few learned and scientific men in Philadelphia, New York, Boston, Baltimore, and Washington City, who are antagonizing the authority and action of the American Medical Association, are superior, in point of intelligence and scientific medical knowledge, to those who will not surrender their honor, but manfully and nobly sustain our national medical organization And let me assure you, that the few who are rendering themselves ignobly conspicuous in trying to obstruct the action of our National Association, are not the real leaders of American thought and opinion in this country, as you seem to think they are, and as they claim for themselves But you may, by distortion of facts and misrepresentation of honest differences of opinion, succeed in defeating the successful meeting of the contemplated International Medical Congress in this country in 1887, and you may disintegrate and disrupt the American Medical Association, but if so, what will you have gained? MEDICAL SOCIETY OF VIRGINIA—SIXTEENTH ANNUAL SESSION

The Medical Society of Virginia will convene at Alleghany Springs, Montgomery County, Va, at 7 30 o'clock, Tuesday night, September 15, 1885 Alleghany Springs is about four miles from Shawsville, on the Norfolk and Western Railroad, twenty-three miles west of Roanoke, and seventy seven miles west of Lynchburg Shawsville is the station for which all railroad passengers must secure their tickets

The Address of Welcome will be delivered by Dr Isaac White, Physician to the Springs, and the Report of the Committee to Nominate Applicants for Fellowship will be presented and acted on Dr H M Clarkson, of Hay Market, Va, will then deliver the Address to the Public and Profession The President, Dr Samuel K Jackson, of Norfolk, will then deliver the President's Address Dr Isaac White, of Shawsville, Va, will read a paper on the Medical Virtues of the Alleghany Springs Water, Va Any business of a general character may next be transacted, and announcements of programme, etc, will be made before adjournment On Wednesday morning, the Society will be called to order at 10 o'clock After the usual form of opening the meeting, the Reports of the Secretaries, the Treasurer, the Committee on Publications, the Executive Committee, the Necrological Committee, the Committee appointed in 1884 to confer with the professions of Virginia, West Virginia, and North Carolina with reference to the organization of a Tri State Medical Association (Dr Joseph A White, Richmond, Chairman), and the Report from the State Board of Medical Examiners, will be severally called for and disposed of New business may be then introduced

The subject for general discussion—Scarlet Fever—will be taken up at 11 30 A M, Dr Thomas J Moore, Richmond, Va, leader After Dr Moore will have opened the discussion, other Fellows and delegates will be entitled to the floor for remarks in the order in which they may be recognized by the Chair It is expected that those who enter into the discussion will prepare their papers beforehand, or else, immediately after the discussion, will furnish notes of what they may have said to the Secretary, in order that the remarks may be correctly entered on the records of the session, and thus prove of lasting value to the Society If any time remains after the discussions till dinner hour, it may be occupied by new business, motions, communications, etc

The Afternoon Session will be devoted to the election of officers and annual committees, including the Necrological Committee for the succeeding term, and of the Fellow to deliver the Address to the Public and Profession in 1886 The election of Honorary Fellows will also be in order, as also the selection of the subject for general discussion, 1886, and the leader in the discussion The place of meeting of the Seventeenth Annual Session is also to be selected

The Night Session will open with the call for Reports on Advances in the several departments of medical sciences, and the following order will be observed until adjournment to Thursday morning, when the call will be continued until the order is completed

1 *Report on Anatomy and Physiology*, by Dr I O Jones, of Harrisonburg

2 *Report on Chemistry, Pharmacy, Materia Medica and Therapeutics*, by Dr M G Ellzey, Washington, D C

3 *Report on Obstetrics and Diseases of Women and Children*, by Dr S W Dickinson, Marion, Va In this section the following papers will be presented (*a*) Successful Treatment of Lacerations of the Os Uteri, without Surgical Operation By Dr Bedford Brown, Alexandria, Va (*b*) Puerperal Septicæmia, especially with Regard to Prophylaxis and Etiology By Honorary Fellow Dr George T Harrison, New York, N Y (*c*) Infanticide By Dr Chas R Cullen, Henrico Co, Va

4 *Report on Surgery*, by Dr H Gray Latham, Lynchburg, Va In this section the following paper will be presented (*a*) Treatment of Hip Joint Disease By Dr Lewis Wheat, Richmond Va

5 *Report on Practice of Medicine*, by Dr Rives Tatum, Harrisonburg, Va In this section the following papers will be presented (*a*) Clinical Notes on Carcinomatous Affections of the Digestive Organs—the Unreliability of Gastric Symptoms as Evidences of Gastric Pathology By Dr R C Powell, Alexandria, Va (*b*) Etiology of Zymotic Diseases By Dr M A Rust, Richmond, Va (*c*) Dyspepsia, with Neurasthenia and Somnolence By Dr M L James, Richmond, Va

6 *Report on Hygiene and Public Health*, by Dr William H Coggeshall, Richmond, Va —his subject being Lessons Taught by the Recent Plymouth (Pa) Epidemic In this section the following paper will be presented (*a*) Cremation By Hon Fellow Dr J Edgar Chancellor, University of Virginia,

7 *Report on Ophthalmology and Otology*, by Dr Philip Taylor, Richmond, Va In this section the following papers will be presented (*a*) Clinical Notes and Practical Observations from Richmond Eye, Ear and Throat Infirmary By Dr Joseph A White, Richmond, Va , Senior Surgeon (*b*) Report of Cases of Tracheotomy in Lupus of Larynx and Diphtheria By Dr Chas M Shields, Richmond, Va

8 *Report on Psychology and Neurology*, by Dr Wm C Dabney, Charlottesville, Va When this order shall have been completed, call will next be made for Voluntary Scientific Papers, Contributions, and Reports Miscellaneous business matters not heretofore introduced or disposed of, will then be in order until the adjournment of this annual session

During this session, the Fellows and delegates in attendance will be the guests of the Alleghany Springs Management, and hence will not be charged for board and lodging On the arrival of each train at Shawsville, transfer coaches will be in waiting to convev passengers to the Springs—about three quarters of an hour's ride Liberal rates of travel have been made with railroads

Eastern bound trains (from Bristol, etc), arrive at Shawsville at 11 58 A M and 10 17 P M Western bound trains (from Lynchburg, etc), arrive at 8 47 A M and 9 03 P M

THE ALLEGHENY COUNTY MEDICAL SOCIETY AND THE INTERNATIONAL CONGRESS

At a meeting of the Allegheny County Medical Society, of Pennsylvania, held August 25, 1885, the resolutions passed at the July meeting were rescinded, and the following preamble and resolutions, offered by Drs E A Wood, J C Dunn and A M Pollock, were adopted by the Society

Whereas, In the unfortunate state of affairs now existing relative to the proposed meeting of the International Medical Congress to be held in Washington, D C , in 1877, it becomes the duty of every physician who has the welfare of the profession at heart to give the matters of difference calm and deliberate consideration, and

Whereas, The basis of organization of the International Congresses heretofore held has been broad enough to include the regular medical profession of all sections and countries, therefore be it

Resolved, That we reaffirm our allegiance to the American Medical Association and its Code of Ethics

Resolved, That we hereby endorse the action of the American Medical Association at its meeting in New Orleans whereby *from its own membership* it added to the original Committee of Arrangements one from each State and Territory and from the Medical Corps of the U S Army, U S Navy, and Marine Hospital Service

Resolved, That this Society endorses the action of the Committee of Arrangements at its recent meeting in Chicago, in deciding that all persons by it appointed to, or recommended for, *official positions* in said Congress, shall be members of Associations in *affiliation with and* therefore *responsible to* the American Medical Association

Resolved, As the deliberate sense of the Allegheny County Medical Society of Pennsylvania, that the proposed meeting of said International Medical Congress should be organized on the same liberal and enlightened foundation as those preceding, and to that end we earnestly recommend the Committee of Arrangements to discard the Code questions as far as *membership* is concerned, and to open the door to all members of the regular medical profession who may comply with the requirements of registration

Resolved, That the Secretary furnish a copy of the foregoing resolutions to the Secretary of the Committee of Arrangements, to the Secretary of the American Medical Association, and that he shall also furnish copies of the same to JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and to the *Medical News* for publication J G CORNELL, Sec'y

Pittsburgh, Pa , Aug 27, 1885

DR EUGENIUS A HILDRETH, one of the most prominent physicians in Wheeling, W Va , died at his residence in that city on August 31, in the sixty-fourth year of his age He graduated at the Ohio Medical College in 1844 He was a member of the American Medical Association, of the West Virginia State Medical Society, and an honorary member of the California State Medical Society and of the Victoria Institute of Great Britain

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 22 1885 TO AUGUST 28 1885

Kane, Jno J , Capt and Assistant Surgeon, granted leave of absence for one month, to take effect when his services can be spared (S O 195, A G O , Aug 26, 1885)

Ebert, R G , Capt and Assistant Surgeon, assigned to temporary duty with U S troops at Riverside Park, N Y (S O 179, Dept of the East, Aug 24, 1885)

Stephenson, Wm , First Lieutenant and Assistant Surgeon, granted leave of absence for one month, to take effect Sept 1 1885 (Ft Niobrara, Neb) (S O 79, Dept of the Platte, Aug 20, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING AUGUST 28 1885

Jones Wm H , Surgeon, detached from the Wachusett, and waiting orders

THE RÔLE OF BACTERIA IN PARTURITION[1]

BY HENRY O MARCY, M D ,
OF BOSTON MASS

About six years ago, in the Boston Gynecological Society, upon the subject of antiseptics in midwifery, I advocated that an instrumental labor should be conducted with all the antiseptic care and precaution of a major surgical operation Then, I found myself without support, now, I do not expect all to accept such a proposition If the subject was by any means settled, or such principles adopted, your attention would not be called to its discussion Few topics in the entire realm of medicine hold to day a deeper or more wide-spread interest, for which we are indebted in America, in no small degree, to the valuable paper by Dr Thomas last year before the New York Academy of Medicine, and the reply of his equally distinguished opponent, Dr Fordyce Barker, followed by a number of other contributors of scarcely less note holding various views The pendulum of thought is never still Upon certain phases of this subject it has appeared to have swung to the opposite, until now, in Harvard and other schools, it is taught that antiseptic injections should be used in all cases of normal labor as a routine practice

Dr Z B Adams, of Framingham, in a vigorous paper read in Boston this past winter, takes strong ground against the routine use of the vaginal douche in normal labor He claims that under such conditions the douche is not only useless, but harmful and injurious Dr Adams cited several cases in which serious results, death even had supervened Five or six fatal cases were reported in the experience of the members present, where it appeared probable that the result was due to the use of the douche The discussion was earnest and long continued, with evidence of wide difference of opinion It should not be difficult, abstractly, to state the problem which in this way at least is one of extreme simplicity If we accept that the fact of parturition normally as a physiological process, that the uterus is a closed aseptic cavity before delivery, one danger to be apprehended lies in the introduction, after delivery has been effected, of a new abnormal or pathological element, into the recently emptied organ This new factor, according to our recent knowledge and belief, is due to the development of a bacterial ferment Many erroneous doctrines are still taught in regard to the processes of reproduction, especially of the placental development

There can be little doubt that the catamenial decidua is the product which is elaborated by the uterine glands This is equally true of the uterine decidua *(decidua vera)* of pregnancy The numerous openings or holes which give the appearance of a sieve to the decidua, only indicate the points corresponding to the orifices of the utricular glands in the cavity of the uterus, which remain fully open to allow the constant passage of the product of secretion. In the early period of pregnancy this secretion is doubtless furnished for the nutrition of the fœtus, later this is elaborated by the complex glandular organ of new formation which we call placenta The serotinal cells are elaborated from the sub mucous layer of connective tissue, and, when separated, as a more or less perfectly formed placenta, there takes place an extensive traumatic lesion of the uterus on account of the laceration of the parts, which leaves bare the uterine tissue which had been covered by the placenta The muscular contraction and rapid shrinkage of the organ reduce the size and cavity, and at the same time aid in hastening the proliferation and expulsion of the broken down and necrosed material

Physiologically, this must be an aseptic process. If the pathological factor lies in the ferment or bacterial poisoning, how may this be introduced? Certainly from without If excluded from the air or any foreign body the uterus, even to its cervical portion, may be likened in its injuries to a sub cutaneous wound When not undergoing change from fermentation the lochial secretion remains a non irritant innocuous fluid, although swimming with broken down and even necrosed cellular debris From this standpoint of view we must take exception to the position assumed by Dr Thomas, above referred to, as well as many others, both in Europe and America

Dr Thomas states "that the lochia is in every case the offensive fluid, that it is made up of dead and decaying animal tissue " True, it contains dead, cast off tissue, and is always a highly albuminous fluid, just the material for the feeding, in their rapid growth, of micro-organisms, when accidentally introduced into this then most efficient incubating chamber Normally, they certainly are not present, and when absent decay or ferment cannot occur.

---

[1] Read in the Section on Obstetrics and Gynecology at the Thirty Sixth Annual Meeting of the American Medical Association
Boston Medical and Surgical Journal Feb 19 1885

Whence come the micro organisms, the ferment necessary as seed? Is it auto genetic, normally found in the parturient canal? If so, why does not every woman suffer in confinement from septicæmia?

Is it likely that of all organic functions, that upon which the continuance of the species depends and which is common to all animal life should, as Dr. Adams pertinently remarks, be the one which acts only under conditions tending to decay and death, that is to say, under conditions of disease? Micro-organisms are usually found in the vagina in health. Would this give us the seed for the sowing of the direful harvest? Evidently such belief pertains to most who have advocated, as preventive, vaginal injections both before and after the completion of labor. This appears to be the weak point in Dr. Thomas's position, and the almost only effective argument used by Dr. Barker against him in reply.

The history of the ages shows that the mortality of normal labor of the entire animal kingdom is very small. No one emphasizes the fact more clearly than Dr. Thomas that in all primal labors, at least, there are as a rule solutions of continuity usually both cervical, vaginal and perineal. In the normal labor the outflow for a few days is constant in current, the drainage of the vaginal canal is usually excellent, and yet this albuminous material, as found upon the napkin or external parts, is generally of a decided odor, and, when carefully examined microscopically, is found swimming with bacteria termo, these most useful of nature's scavengers, the omnipresent agents for taking to pieces and refitting for other uses albuminoid compounds. In this form of micro organism we surely rarely have danger, and when we consider the normal conditions present we readily see why we do not find these growths in the uterine cavity. Although I am as earnest an advocate for cleanliness as any other, this fact will explain why, amid filthy surroundings, the unwashed, unchanged, uncared-for woman so very generally makes a good convalescence. In a theoretical way it is possible for us to consider that the bacteria-termo of decomposition serve a useful end, by utilizing and exhausting the material otherwise efficient to feed an army of most dangerous enemies.

Dr. Thomas advises a careful disinfection, closing and sealing of all perineal and vaginal rents. Most excellent advice, and surgically very important, which we hope to see generally adopted, but, when we remember that he advocates this with the distinct object of lessening the danger, or obviating the cause of puerperal fever, we can but think he becomes unintentionally misleading, and in so far fails of his purpose, for we cannot believe that Dr. Thomas would teach that septic absorption from the injuries of the ostium vaginæ is the cause of puerperal fever. At the most, these are open wounds of tissues of comparatively little importance, and would certainly endanger the patient in a degree no greater than after operations for perineal restoration, and we do not suppose our distinguished friend would consider a general dangerous septic poisoning at all likely to supervene upon perineal repair.

The above argument would not hold good in laceration of the cervix, since this is the part of an organ which has undergone a most marked physiological change. The vascularization of the uterus and pelvis at term is extraordinary, the lymphatic system has become equally developed until the physiological state is one nearly akin to certain well recognized pathological conditions. However, it is not shown that puerperal fever is especially liable in primal labors, and yet it is generally accepted by all that cervical lacerations are far more frequent, in a certain degree rarely absent, in first confinements.

It would seem that even here something more is wanting than the initial lesions under ordinary conditions to induce the dreaded dangers incident to so-called puerperal fever. Careful cleanliness before and at labor should be enjoined, a strong antiseptic vaginal douche before delivery may be wisely advised. The circumfusa of the patient is by Dr. Thomas taken into account. A specially prepared room, with every surgical precaution, an aseptic atmosphere is emphasized and enjoined, even to wiping the furniture with carbolic or bichloric solutions. This is certainly safe, and of no very great consideration so far as expense or trouble is concerned. It is a consideration, however, unless really demanded, if we may not cause thereby serious foreboding and unnecessary nervous trepidation on the part of the patient. This would certainly not be required if the delivery was normal, and normal labor is accepted as an aseptic condition equivalent to a subcutaneous surgical operation.

Let us suppose the labor no longer remains normal, but that manipulative interference becomes necessary. Here the entire phase of the question is changed, and under these conditions I would emphasize the use of the most thorough antiseptic surgical precautions. Our proceedings are now subject, in large measure, to atmospheric exposure, and here we need an aseptic atmosphere. In home, as well as hospital, let its purification be enforced. I have for years in instrumental labors believed in and used the spray. It certainly can do no harm, it may be of the greatest value. Infinitely more important, however, is the aseptic state of the operator. If the physician has been attendant upon infectious diseases, he should take a bath, change his entire clothing, pay particular attention to his hair and beard, and scrub his hands and especially under the nails with 1–20 carbolic solution, or 1–1000 mercury bichloride. The same care must be used with instruments. In all cases where the placenta has been detached manually, let the uterine cavity be antiseptically treated, ergot given and the uterus kept in control until firmly contracted. Then iodoform may be wisely introduced into the vagina, and a compress applied externally, moistened by a reliable antiseptic solution.

Why are these precautions dogmatically asserted as arbitrary rules? Without especial review, simply because they are based upon the same general principles which govern in surgery. Then are puerperal poisonings and surgical poisonings essentially the same? Of this there can be little doubt. As I have insisted above, the bacteria of decomposition have nothing in probability of casual relation thereto. It is the round cell growth, the micrococcus, which is active here as in the septicæmia of wounds. The bacteria of decomposition do not readily reproduce in the blood of animals, and when injected therein rarely do more than serve as a more or less active chemical irritant. This is not true of the micrococcus. Under favorable conditions, which are so very general in the pregnant state, they effect lodgment, colonize with a rapidity entirely inconceivable. Such seed introduced into such a favorable soil must yield an abundant harvest.

The planting ground, however, is rarely the vagina, but is found in the uterine cavity. It is hard to conceive of an incubating chamber presenting more favorable conditions. The albuminous fluid furnishing abundant food, the heat point steadily maintained, open sinuses, lacerated vessels, denuded walls through which ramify an abundant network of lymphatic vessels, all furnish conditions for generation and absorption rarely equalled. Carried along with the lymphatic stream, they are distributed to neighboring and often distant organs. They not seldom form thrombi in the veins, and as such are carried into the circulation.

The micrococcal development is all the more dangerous, since it is accompanied by no marked odor, and I fear many have been and are accustomed to determine conditions by such imperfect and unsatisfactory methods. When once infected have we means within our power for remedying the evil? Here again the conditions are much the same as in surgical septicæmia. Washing out the uterus does not prevent the mischief already done to the neighboring tissues. Dr. Lusk most tersely and forcibly puts it as follows: "The douche, however, is not infallible. In cases where there has been inoculation of the round bacteria, they often invade the tissues beyond the original lesion, and it is of small avail to wash out the uterus when the victorious army has advanced far away from the point of attack. Washing the arm daily after vaccination does not prevent the development of vaccinia. Washing out the uterus after the pelvic tissues are infiltrated with septic microspores may cut off the reenforcements, but does not prevent the progress of puerpereal septicæmia. I would advise, therefore, not to continue the uterine douche in cases where the results of the first thorough injection furnish the evidence of its importance."

In my own experience I have treated the uterine cavity as I would an infected, suppurating, sloughy wound. I do not hesitate carefully to remove with blunt curette any irregular placental masses from the uterine cavity, and in a number of instances have applied thoroughly the liquified crystals of carbolic acid. This, I believe, may be safely used, since the acid coagulates the albuminoids and is thereby not readily absorbed, while it acts as a local stimulant to the surrounding tissues and makes them less absorbent. I have also often introduced a considerable quantity, fifteen to thirty grains of iodoform, within the uterine cavity and allowed it to remain.

The relation of erysipelas to puerperal fever has long been suspected, and was first advocated as cause in Boston. An unfortunate series of cases occurring in the practice of a brother physician, within the year, is worthy of notice. Following a case of erysipelas early in January, there supervened in his practice five fatal cases of puerperal fever, the last developed at about the tenth day, erysipelas following what seemed a slight abrasion in the middle line over the coccyx up the back, and then diffusing laterally, until it became general, and before death had extended over quite the larger portion of the body. I inoculated sterilized bulbs at the bed side with fluid taken with much care directly from within the cervical cavity. Micrococci in a pure culture were reproduced in rapid growths, and in appearance they could not be differentiated from the micrococci in the cultures from the blisters of erysipelas.

Too much importance has undoubtedly been placed upon the use of injections. We think Dr. Adams and others have shown that they are in normal labor at least of doubtful benefit, and are not seldom dangerous. The douches doubtless often carry the very infection for the destruction of which they are employed. Who of us have not seen the use of dirty unboiled water with serene composure, because, forsooth, a little of some doubtful antiseptic had been added thereto? Danger lies even in the hand of experts of world-wide fame. Under date of November 14, 1884, Dr. H. G. Bigelow writes me from Berlin that Schroder has lost three cases from intra-uterine injection; in the last case 1-1000 mercury bichloride was used. Dr. Adams pertinently remarks that one set of authorities advocate the use of one kind of syringe, and another, laying blame to the instrument instead of the method.

We have already attempted to show that in normal labor it is not required, while it is too plainly apparent that after the disease has developed and micrococcal poisoning has supervened the intra-uterine douche too often fails to secure the desired result. Earlier I believed differently, and gave much thought to the perfecting of a double soft rubber injection tube for this very purpose. Experience in Europe as well as in America, clearly teaches the great importance of the subject, and the salvation of lives in large numbers has undoubtedly followed the more or less general wise precautionary measures adopted.

Under date of March 25th, 1885, Dr. E. W. Cushing writes me from Berlin, "The acceptance of the germ theory is universal, and its application is most incredible in thoroughness. The habit of washing out the vagina after child-birth, in cases which give no evidence of infection, has been entirely given up in the well regulated German hospitals as unnecessary where proper care and cleanliness prevails, the washing both inside and outside being done with the utmost thoroughness *before*, not after parturition."

A better general understanding of the subject will aid in carrying on the good work. "I will show you my faith by my works," saith the apostle of old. One must understand the great underlying principles of antiseptic surgery, and accept them *in belief* in order to carry them wisely into effect. Let the facts be adduced and the reasons clearly shown for the innovations demanded, else they will be relegated to the systems and fashions of the fallacies in the medical art.

DETERMINING ERRORS OF REFRACTION BY DOUBLE IMAGES AND BY PARALLAX[1]

BY T. E. MURRELL, M.D.,

OF LITTLE ROCK, ARK.

By Double Images.—In studying the laws of refraction as applied to the eye, it occurred to me that two opposite peripheral beams of light in the pupil could be made available in determining the posterior focal point of the eye relatively to the bacillary layer of the retina. This can be easily accomplished by using a disc or card with two small perforations in it, large enough to give distinctness of vision, and close enough together for both to fall within the area of the pupil. In order to prevent lapping on the retina, it is necessary to use a point of light for observation, which should be about twenty feet distant from the observer. A pin hole in a card over a candle, lamp or gas flame, or over a window against the sky, or, better still, as the room does not have to be darkened, a small silver globe hung opposite to a single window opened towards the sky, gives the necessary point of light. In the toy stores are kept glass globes about two and a half inches in diameter, hollow, and brightly silvered inside, which give a very bright small surface when hung opposite to a window, distinctly visible from all parts of the room, that answer the purpose admirably. In emmetropia, with the accommodation in a state of rest, all the light that enters the eye through the pupil from a distant point is focused in a single point in the retina.

It does not matter through what part of the pupil any isolated ray may pass, it is converged to one and the same point in the retina as any and all other rays from the same source. Hence, if two slender beams from opposite margins of the pupil are caught and others excluded, they will meet in one point in the retina and give a single image. In emmetropia, therefore, in viewing a distant point of light through the double aperture, it appears single. In myopia, the two pencils cross in front of the retina and meet the bacillary layer at separate points, hence the point of light is seen as two points. In hyperopia, the two pencils of light reach the retina before meeting, and likewise give two distinct visual impressions of the distant point of light. The appearance is the same, whether for excessive or defective refraction, but they may be readily distinguished by slipping the edge of a card over one of the apertures, when, if myopia exist, the point of light corresponding to the aperture covered will disappear, but in hyperopia the opposite point will disappear, or, by holding a spherical lens before the eye, when the two points will approximate if it is a correcting lens, and separate more widely if not. The lens that blends the two points into one is the correcting glass for distant vision.

A space of one millimetre between the apertures in the disc causes a separation of the points of light at a distance of twenty feet, about sixteen millimetres for each dioptrie of abnormal refraction. By ascertaining, then, from the person under trial the apparent distance between the points of light, the degree of error can be approximated.

In astigmatism it is only necessary to revolve the disc before the eye so as to cross the different meridians of the cornea in order to ascertain which meridian, or meridians, is in fault. Spherical lenses can be used for finding the correcting number. When found, the cylinder, or sphero cylinder, should be put in the trial frame and the disc revolved, to see if there is a single point of light in all meridians; if so, correction is perfect. For convenience, I use a circular disc of blackened brass, which fits into the trial frame, so that it can be easily revolved, and the faulty meridians readily found. The most convenient size for the apertures is about one millimetre, and the distance between them one millimetre. In some cases, apertures of half a millimetre in diameter work best, especially in excessive ametropia, and in very small pupils.

I have worked out a number of cases of myopia, hyperopia and astigmatism by this method with, in most cases, the greatest ease, and chosen the correct glass from the trial case without other aid. The two apertures should always fall within the pupil, else it will lead to error. When both apertures are seen through, two circles appear to lap before the eye, and vision should be through the lapped portion.

Some persons are so awkward and unintelligent as to confuse the examiner, but they would prove equally troublesome by any other subjective method. Some preliminary instruction, therefore, becomes necessary, as in the use of other means. By this device an error of half a dioptric is easily detected.

Some time after I had been using the double aperture disc for solving ametropia, I, for the first time, came upon an account of Scheiner's experiment to demonstrate accommodation. The device he made use of was identical with the one here presented, but he only used it as an experiment to prove the accommodation of the eye, as it may still be practically applied in determining the punctum proximatum.

By Parallax.—If a single small aperture in a card be moved somewhat rapidly back and forth in a straight line across the pupil, at the same time that fixation is on some object twenty feet or more away, the object will appear motionless if the eye is emmetropic, but will seem to move if myopia or hyperopia should exist. In myopia, the object will appear to move in a direction with the card, while in hyperopia, the reverse is the case. In astigmatism, it is only necessary to move the card in a line corresponding with the faulty meridian, to determine the existence and kind of refractive error. The explanation of this parallax will be readily understood when the laws of projection are applied. Projection, as is well known, is from the retinal image through the nodal point of the eye. Since, therefore, all the light from any distant point that passes through the pupil in an emmetropic eye with accommodation in abeyance, is conveyed to a single point in the retina, it follows that all projection for every ray that enters the eye from that point will be in one line, hence the object will appear motionless, however much the different entering rays may be changed by moving the aperture In myopia, the focal point of the eye lies in front of the retina, and the pencils which enter the pupillary area cross here and separate before reaching the retina, so that when the small aperture is moved across the pupil, the retinal image will move in the opposite direction, projection being, for this reason, in the same direction

---

[1] Read in Section of Ophthalmology and Otology at the Thirty Sixth Annual Meeting of the American Medical Association.

In hyperopia, all the rays that pass through the pupil form a cone truncated at the retina, and each retinal point within this area will correspond with a like position in the pupil Hence, when the aperture admitting a small beam of light is moved across the pupil, the retinal image will move with it, but as the image travels in one direction the movement of projection will be in the opposite direction There fore, in hyperopia the object will appear to move in a direction opposite to that of the card

The amount of displacement of the object fixed upon twenty feet away is for each dioptrie of ametropia about sixteen millimetres per millimetre pupillary diameter So that, with the average sized pupil, the displacement becomes quite conspicuous, even in small errors This, therefore, is a very delicate test, being sensitive to an error of one-fourth of one dioptrie or less

Of course the same rules apply with reference to the necessity of paralyzing the accommodation as by any other other method The larger the pupil, the more sensitive the test If, in astigmatism, the card is moved in a meridian obliquely to the faulty meridian in the eye, the object will appear to move in the dian, or obliquely to the direction of the card In irregular astigmatism, the object will simply appear unsteady, or to jump in different directions

In using this test *by parallax*, the card or disc may be moved to and fro across the pupil by the party examined, but awkwardness on the part of many persons renders it important to use in astigmatism some mechanical device by which the movements of the aperture can be made uniform and in a line with any desired meridian I have had constructed a circular brass disc, blackened, to fit into the trial frames, having a movable centre piece regulated by stops, and in which is the aperture to look through, which can be easily revolved or oscillated by a touch of the finger The aperture should not exceed one millimetre in diameter

Either of these methods will often prove a great aid to other methods in determining not only the refraction of the eye, but in proving the correctness of the glass If, with the correcting lens before the eye, there are two points of light in any meridian by the one method, or a parallactic movement of any distant object by the other, the glass is not correct

The method by parallax is especially serviceable in high degrees of amblyopia, where the exact refraction can often be determined when vision is so low as to render the largest letters of the test type indefinable It is also useful in establishing the existence of amblyopia in those cases where the examiner is sometimes puzzled to know how much of the defect still not overcome is due to error in the glass, or how much to deficient perceptive power To determine at once the existence of any error of refraction the method by parallax is the simplest, surest and quickest of all methods, since a pin hole in a card and any distant object to fix on constitute all the appliances necessary for the examination I hope I am not to be understood as supplementing by these simple devices the use of the ophthalmoscope, test type or diagrams in the solution of ametropia Far from it I merely claim for them a usefulness that entitles them to a place in the specialist's trial case At least they possess the merit of simplicity, inexpensiveness, and strict conformity with scientific principles

---

A CASE OF HEREDITARY GLAUCOMA[1]

BY HERBERT HARLAN, M D,

OF BALTIMORE MD

That glaucoma is often hereditary, and that when hereditary, it tends to appear at an earlier age than common, was recognized by von Graefe as long ago as 1869,[2] but that the disease should appear in five successive generations before the age of 20, is, I think, worthy of record, and is my excuse for presenting to you the history of the otherwise sufficiently common case which follows

Case —C E B came to me from one of the towns on the eastern shore of Maryland, March 24 The patient was a timid, nervous, not very intelligent, but well developed girl of 17 years Her sight had been failing a little more than a month, and more rapidly the previous week For several nights had seen circles of colored light around the lamp The nearest approach to pain had been a sense of discomfort The eyeballs were prominent, the pupils slightly dilated, V O D $\frac{20}{100}$, V O S, $\frac{20}{100}$— Jaeger No 1 with each eye for a moment, but with marked discomfort T 1 + The ophthalmoscope revealed a whitish and deeply excavated optic nerve, vessels numerous, and veins dilated and tortuous, but there was no pulsation except on slight additional pressure Diagnosis, chronic glaucoma

Inquiry brought out the following family history Her mother, who accompanied her, is 49 years old, and absolutely blind Both anterior chambers are obliterated, and the pupils closed She states that at 19 her eyesight began gradually to waste away She saw halos around the lamp A year later had inflammation in the eyes which the doctors called cold, and treated with drops and blisters After a while, the eyes got better Then another attack of inflammation came on, and she has been blind ever since Never at any time was there much pain The mother's father lost his sight in the same way, beginning at the age of 18 This is also the history of the maternal great grandmother and great-great-grandfather I was unable to trace the family history further back, but from that given, there can be little doubt that chronic glaucoma has been transmitted in direct line for at least five generations, the age of onset being about the same A maternal uncle at 35 years had pain in his eyes and head, and in three years his sight was entirely gone A maternal aunt who saw perfectly till she was 18 years old, and never complained of pain, was suddenly found by the family to be blind She died three years later Two uncles and an aunt, all over 55 years of age, see well One cousin, now at a blind asylum, began to lose her sight at 16 Sight in her left eye was gone before it was found out The other slowly followed Never complained of pain Another cousin was operated on four years ago by an oculist of Baltimore One eye was removed altogether, and on the other an iridectomy was done, and with this she now sees

---

[1] Read in the Section of Ophthalmology and Otology, at the Thirty Sixth Annual Meeting of the American Medical Association

A f O XV, 3 page 228

For the case now under consideration I advised an iridectomy, and the following day, under the influence of muriate of cocaine, I performed the operation on both eyes, excising a large piece from the upper segment of the iris in each I used a lance-shaped knife, and although the patient was restless and fixation of the eyeball was exceedingly difficult, the operation was perfectly smooth Atropia was instilled, the eyes bandaged, and the patient put to bed Two days later, on examination with a candle, I found the right eye clear, but in the left the lens was hazy

To be brief, at the end of ten days, as a result of the operation in the right eye, all sense of discomfort was gone, $V = \frac{20}{20}$, comfortable Jaeger No 1, and the ophthalmoscope showed all the congestion of the fundus to have disappeared In the left I had a traumatic cataract, doubtless due to the operation, but just when or how caused I do not know The patient then had an attack of mumps, and was discharged from the hospital, and on April 13 was re-admitted and operated on for the removal of the opaque and murky lens From this last operation she made a good recovery, and six days after, on the day of leaving home to attend this meeting, the pupil was clear, there was no discomfort, and she readily counted fingers with the left eye

---

SUGGESTIONS ON SOME SYMPTOMS OF RENAL DISEASE, AND THEIR MANAGEMENT

BY CHARLES W PURDY, M D,

OF CHICAGO HON FELLOW OF ROYAL COLLEGE OF PHYSICIANS AND SURGEONS KINGSTON

I desire first to draw attention to the mode of action, and range of utility, of certain diuretic agents in the treatment of renal diseases This seems the more appropriate at this time, inasmuch as the widest difference of opinion exists among authors, as to the propriety of the general use of diuretics, in the treatment of nephritis, both in its acute and chronic forms Some are accustomed to rely largely on the use of these agents in the treatment of those diseases accompanied by albuminuria, while others, more notably Senator, of late condemn their use as altogether injurious It cannot of course be denied but that the indiscriminate use of diuretics is capable of doing harm in some cases, but this is equally true of most other medicines, and it only teaches us that they should be given with a definite purpose in view, and withheld in those cases where experience has taught that they are useless, or harmful

That diuretics not only do not always prove injurious, but in many cases prove highly beneficial in the treatment of albuminuria, has been testified to so frequently by those whose experience peculiarly fits them to judge intelligently, on this question, that it seems impossible to doubt the proposition that they have a definite range of utility It is my present purpose to point out some of the more obvious indications for the use of these agents in treating albuminuria, and to call attention to the special agent appropriate to each case, on pathological, physiological, and chemical grounds

First then, if the actual quantity of urine falls seriously below normal, we know from ample experience that the patient is subjected to very grave dangers and, that these dangers will be directly increased in proportion to the actual diminution in the quantity of urine secreted It is obvious that diuretics are imperatively demanded in such cases for at best we can only substitute the action of the kidneys, by that of the skin or bowels, for a short time, and that in a very imperfect manner It therefore becomes our duty to increase the secretion of urine in such cases by such agents as are most efficient, and at the same time the least embarrassing or injurious to the kidneys themselves In order to be able to accomplish this intelligently, we must study the cause of the diminution or suppression in each case

There are chiefly three pathological causes of diminution, or suppression of the urine met with in the course of renal disease First,—congestive inflammation of the glands, resulting in (a) blocking up of the secreting tubules with colloid matter, counteracting the blood pressure which causes filtration of the urine, and preventing the escape of the latter, (b) inflammatory changes in and around the glomerule, which interfere with the renal function, and prevent the secretion of the aqueous urine Such are the causes of anuria in all forms of acute Bright's disease, whether arising from cold, scarlatina, or pregnancy, *and which lead up to dropsy, and all those* secondary complications arising from retained urinary derivatives in the blood

Secondly, we have lowering of arterial pressure, which lessens the tension in the glomerule to a point where filtration of urine becomes diminished, or more rarely, altogether arrested Such conditions we find sometimes present in late stages of granular kidney, where the heart affection has outrun the renal, passing rapidly through the stages of hypertrophy, and dilatation, into fatty change (the legitimate result of hypertrophy if it lasts long enough) In the stage of collapse in cholera, we have the same lowered pressure, and suppression, while in mitral disease of the heart the same thing also occurs to a less extent, resulting in diminution, short of suppression of the urine

Thirdly, the secretory structure of the kidney may become so largely destroyed through disease, that sufficient of the gland does not remain intact to carry on the function of the organ as a whole, and the urine falls periodically, or constantly below normal This condition is met with in the last stages of atrophy of the organs from cirrhosis, or interstitial nephritis so called. New growths, and extensive emboli, may produce similar results.

Now, in the first case, where the secreting tubules of the organs are completely blocked up with colloid exudations, the obvious indications are to clear these away, before we can hope to reestablish the urinary secretion. How are we to accomplish this object? We know that albuminous substances are soluble in alkaline solutions, and we know that we are able to render the urine alkaline by the administration of certain neutral salts, as the acetate and citrate of potash. The indications are perfectly clear then, that these neutral salines are the agents *par excellence* to direct against the conditions named, *to wit*, acute nephritis. Once the urine is rendered alkaline the tube casts are dissolved, either completely, or to the extent that they are able to pass the narrow constructions at Henle's loops, and thus become washed out with the urine. I am not aware that any one has yet suggested, that the action of these neutral salts is largely a chemical one, and, through rendering the urine alkaline, effects a solution of the colloid plugs which block up the renal tubes. That such however is no mere theory, I have satisfied myself by observing the behavior of tube casts in urine rendered alkaline outside the body, where they are dissolved after a few hours' standing. Further testimony in the same direction is afforded by the fact, that tube casts are rarely found in alkaline urine, no matter what pathological condition of the kidneys exist at the time it be passed.

Experience has strongly confirmed the superior efficiency of these agents as diuretics in acute Bright's disease. Nearly all authors give them the preference in such cases. Thus Dr. Roberts, in his last edition writes: "in a considerable number of cases of acute Bright's disease, coming under my treatment early, I have obtained almost invariably the best results by the administration of citrate of potash. And *in no instance where the urine has been rendered alkaline*, in the first week of the complaint, have I observed the more severe uræmic symptoms, or secondary inflammations." The saline diuretics are probably the least of all stimulating to the renal epithelium, and consequently least irritating to the kidneys, which still further fits them for use in acute cases. In cases then of acute nephritis, attended by diminution or suppression of urine, the best results may confidently be expected from the administration of the citrate or acetate of potash, in sufficient doses to maintain the urine alkaline. I am aware of but one exception to this rule, namely, in the case of scarlatinal nephritis. In the latter case, in addition to the blocking up of the tubules, there is more inflammatory swelling of the Malpighian glomerule than in any other form of acute nephritis. The products of inflammation infiltrate the glomerule, producing a homogeneous swelled mass. Leeching the lumbar region, followed by fomentations and cathartics, are therefore demanded in these cases in addition to the saline diuretics, more urgently than in other forms of acute nephritis.

In the second class of cases, where the urine is diminished owing to lowering of arterial pressure, the indications are more obvious. Under such circumstances we may expect the best results to follow the use of heart tonics, as digitalis, convallaria majalis, adonis vernalis and strophanthin. In other words, we get the best results by treating the heart disease, upon which the renal complication depends.

In the third class of cases, where the urine is diminished as the result of destruction of large areas of the kidney structure, the remaining sound portions of the gland must be made to do the work of the entire organ. Certain fortunate circumstances favor us in such cases. First, the capability, unlike the heart and most other vital organs, of the kidneys of work far beyond the requirements of the system, so that a comparatively small portion of the organs may perform the function of the whole, if only the remaining portion be sound. Happily in these cases under consideration, the portion of the glands unencroached upon is usually normal, or nearly so. In these cases we must employ our most active diuretic measures, in order to stimulate the remaining portion of the kidneys, up to a point where a normal quantity of urine may be secreted, or rather as much as will permit the functions of life to proceed without interference if possible from a renal source. Digitalis, convallaria, and heart tonics are indicated as before, but in this case, to maintain the blood pressure *above* normal. With these measures are to be combined such agents as juniper, scoparium, and squill. Indeed such cases as these unfortunately leave us little room for choice of agents to be used; the urgency of the case demands all the resources we are capable of bringing to bear against renal inactivity.

With regard to the use of diuretics in the treatment of albuminuria, where the quantity of urine is normal, I am inclined to think with Senator, that their action is harmful, or at least unnecessary, and that they are best avoided.

The next point I desire to mention, is the value of high vascular pressure, as a diagnostic symptom of renal diseases. I say renal diseases purposely, as I quite recently came to know that it accompanies diabetes mellitus, as well as chronic Bright's disease, and hence, we have an additional reason for examining the urine, when the sphygmograph indicates high vascular pressure, as we are liable to find sugar in the urine in such cases, as we are albumin.

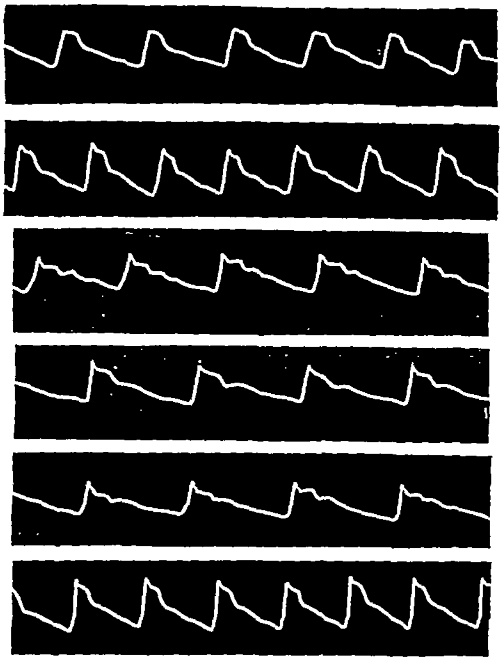
To the late Dr. Mahomed, of Guy's Hospital, we are indebted for first pointing out the constant coincidence of high arterial pressure, with chronic Bright's disease, and moreover, that it is an extremely early symptom of that disease, being very frequently present long before albumin makes its appearance in the urine. This symptom, as Dr. Mahomed showed, is not only valuable as a diagnostic, but also as a prognostic sign, as it points very strongly to chronicity of the disease. I have been in the habit of relying much on this sign of late, in making up my diagnosis of chronic Bright's disease in its early stages, but, as I have dwelt upon its characters, and value in these cases at considerable length in a recent publication,[1] I need not here repeat them.

With regard to high arterial pressure connected with diabetes mellitus, several very important questions at once arise, which the future may prove of practical value, as well as of considerable interest, both in an etiological and therapeutical point of view. Thus the constant hyperæmia of the liver pointed out by Dr. Pavy as accompanying diabetes, may bear a very important relation to the tension of the arterial system, which I have just spoken of as accompanying the same disease. The obstinate nature of coughs, and the insidious manner of approach of bronchial and pneumonic inflammation in diabetes, would seem clearer in its causal relations, if we take into consideration acccompanying high arterial pressure, and this suggestion appears in stronger light still by analogy, when we reflect on the similar tendency in chronic Bright's disease. The frequent appearance of albumin in the urine of diabetic patients, without marked lesions, is more readily explainable on the ground of exalted vascular pressure, as we have the same slight albuminuria in interstitial nephritis, as many think, from the increased blood pressure alone, since the renal lesions are so slight, or even apparently absent in the early stages.

---

[1] Chicago Medical Journal, May, 1885.

But the most practical and valuable results which may possibly be the outgrowth of high vascular pressure, if it shall prove, as I believe, that it constantly accompanies the diabetic condition, would be in the direction it may shape the therapeutics of the disease. Thus if high arterial pressure is closely associated with the cause of the disease, we may expect to derive benefit by a cathartic course of medicines, which lower the blood pressure. With regard to the cause of high arterial pressure of diabetes mellitus, my own investigations thus far only enable me to say that it is not due to the presence of sugar in the blood, as one would perhaps naturally suppose, for in three of my cases which were put upon successful treatment, causing a complete disappearance of sugar from the urine, in pathological quantities, the exalted vascular pressure continued uninfluenced. These facts would tend to show, that the cause lies deeper than the mere presence of sugar in the circulation, possibly it may underly certain conditions of the system from which spring in some cases diabetes mellitus, and in others, chronic Bright's disease, such as imperfect tissues metabolism. We have already referred to very similar phenomena which are quite common to both diseases, as chronic cough, slight albuminuria, and many others might be named, such as diarrhœal tendencies, the large amount of uric acid in the urine, the tendency to death by coma, etc., while moreover, both diseases are most prone to arise during the same periods of life, being most common between 30 and 60 years. I append below examples of pulse tracings from diabetic patients of mine, in which it will be observed, that the characters are exactly similar to those accompanying chronic Bright's disease' namely, those of high arterial pressure, and I may add, in the of course limited number of cases coming under my observation I have never found these absent in diabetes mellitus.



Lastly, I desire to refer to the question of uræmia, as this has always carried with it the deepest interest in the consideration of renal disease. In no field of scientific research, has persistent and indefatigable investigation been less rewarded by satisfactory results. It has defied successfully the fixation of its cause upon every single element of the urine, normal, and abnormal thus far, till practically we are not much wiser as to its etiology than were the first observers, who noted the appearance of its remarkable phenomena, as a constant result of suppression of the urinary secretion. It is true, we possess more knowledge of the various phases of its manifestations on the organism, and, moreover, we know something more as to its successful management, and anything that can add to the latter, is always of practical interest. For some time past (since the observations of Rommelaere, of Brussels) an impression has prevailed that the responsibility for the cause of uræmic manifestations, does not reside in any single element of the urinary excretion, but rather in several of these, if not indeed the whole compound. Quite recently Professor Bouchard, in a communication to the Société de Biologie, has pointed out that normal urine is very toxic, when injected into the veins, even in very small quantities (this has been denied by previous observers), and from a series of experiments he concludes that several poisonous alkaloids reside in several of the urinary constituents. These however have not yet been isolated, and consequently their antidotes have not been ascertained, so that we are not much nearer practical results in the management of the grave complications from this source.

That the cause of uræmia is a toxic one, is generally admitted, and all the facts go to confirm this assumption. That the toxic agent, or agents, either reside in the urinary constituents, or their derivatives, is evident from the fact that when the urinary secretion is retained in the system a sufficient length of time, the uræmic phenomena follow, and moreover, the latter subside on the reestablishment of the urine if it continues Now so far as the nervous system is concerned, this toxic influence seems to direct itself sometimes most intensely against the medulla and motor centres, and if sufficiently concentrated, tonic convulsions are the result In other cases the sensory tract of the brain suffers the most profoundly from the toxic influence, and death may result from coma, pure and simple

With our present knowledge, then, of the causes, nature, and effects of uræmic phenomena, what are the most effective agents we are able to bring to bear against this grave disturbance? With regard to the motor disturbances induced, the agents which have heretofore proven of the most service, have been chloroform, chloral hydrate, bromides, venesection, and (apparently) morphine[1] administered subcutaneously In this class of cases, I should in future be strongly inclined to make use of the calabar bean extract on physiological grounds I am not aware that it it has been used in such cases, but it would be interesting to know if practical results bear out its physiological indications The eclampsia of pregnancy should be its more legitimate field of curative action

While such agents as we have just named may sometimes control convulsions, and thus preserve life, yet, they all[2] have a limited range of action, influencing only the toxic effects on the brain and nervous system, while the poisonous influence pervades the system at large, and is equally liable to overcome some vital organ and cut life short It is evident, therefore, that such do not aim at the uræmia itself, but rather at its effects, and that only in a limited field What we yet require, is agents that will modify the toxic principle itself in the system, in other words, those which will act chemically, instead of physiologically, in order to modify or control uræmia in its totality So far as my own experience is concerned, the only remedy which has seemed to me to exercise such action to any appreciable extent, is the subcarbonate of iron Fortunately, this is a remedy peculiarly fitted on other grounds, for use in the vast majority of conditions associated with uræmia It was indeed the latter circumstance, that first led me to notice its influence over uræmic symptoms A patient having passed through uræmic convulsions, still exhibited threatening symptoms for more than a week after, notwithstanding the daily use of hot air baths, purgatives, and chloral hydrate Being very anæmic, I ordered the iron carbonate in full doses, and his uræmic symptoms subsided so rapidly that my attention was directed to the possible agency of the iron in the favorable result

My next trial of it was in the case of a patient suffering from granular kidneys, and marked hypertrophy of the heart, the result of nephritis in two successive pregnancies Living at some distance, the patient was only able to come to town about once a week On one of these visits, she was suffering from rather sharp uræmic manifestations, as severe headache, nausea, etc She was given iron subcarbonate in large doses, and directed to report, if not improved in two days She returned in a week stating that the headache, nausea and other unpleasant symptoms had promptly subsided on the use of the iron Unfortunately the subcarbonate was discontinued, and death by uræmia soon after followed. The less urgent manifestations of uræmia, such as occipital or frontal headache so common in these cases, I have repeatedly observed disappear (usually in a couple of days or sooner) under the use of the subcarbonate I shall attempt no further explanation of the *modus operandi* of the subcarbonate of iron in such cases than to suggest that it is probably chemical, in some way modifying the toxic agent in the blood, possibly by oxidation In my hands, the best results seem to follow very large doses of the subcarbonate (from 20 to 30 gms) repeated every two or three hours

We have said nothing thus far of the eliminative treatment of uræmia, or of the means of getting rid of the accumulation of the toxic matters through the natural channels of the system The results of these methods of treatment, have been so obviously beneficial, that there is little room for argument on the question Indeed, all treatment for uræmia must sooner or later converge to this point, if we hope for the machinery of the system to become capable of permanently freeing itself from clogging, without outside assistance The kidneys themselves being the natural outlets for these toxic elements, it is self-apparent that the best results will follow the free establishment of the urinary secretion After what I have already said in reference to diuretics in the beginning of this paper, it will be unnecessary to add more upon the subject here

The skin deserves special consideration, however, in this connection, as it is capable of being stimulated into very free eliminative action, under the influence of certain agents The most efficient of these are hot air baths and jaborandi, or the active principle of the latter, pilocarpin The most thorough action obtainable is by means of dry hot air, in preference to vapor baths, or wet packs, for the reasons that evaporation from the skin is vastly more rapid in dry than in moist air Of scarcely less importance is the fact, that the bodily temperature is by no means so much exalted by dry, as moist hot air, for obvious reasons One precaution is necessary in the use of all hot baths, either aqueous, or atmospheric If the symptoms of uræmia are very active, more especially as is often the case here, the temperature is elevated, to say 101° F , or over, the hot bath is apt often to precipitate convulsions, or, as I have likewise witnessed, active uræmic intoxication Under such circumstances then, it will be safer to establish free catharsis first, which will lessen the urgency of uræmic symptoms, and lower the temperature, after which, the hot baths are rendered both more safe, and efficient

---

[1] It may be justly questioned if we have a right to risk the use of morphine in the necessary doses to control tonic spasms since ample experience has shown the frequent dangerous effects of opium on the renal conditions which most commonly give rise to uræmia

[2] We may perhaps except venesection but unfortunately this is inadmissible in most renal diseases giving rise to uræmia.

Jaborandi in its action on the skin does not possess the above mentioned disadvantage, though it has some contra-indications which it is well to bear in mind It is frequently very depressing to the hearts action, producing marked prostration, and moreover, it is frequently quite irritating to the respiratory system The latter fact is deserving of the more importance in consequence of the fact that bronchial and pulmonary complications are peculiarly liable to arise during renal incompetency I have witnessed, as I believe, the comatose symptoms relieved by means of philocarpine injections, but only to hasten the actual development of previously threatened pneumonia, followed by death The use of jaborandi should be limited to cases which evince no bronchial, pulmonary, or cardiac tendencies, thus the eclampsia of pregnancy especially constitutes an appropriate field for its action

Finally, the intestinal tract is a peculiarly efficient avenue of escape for these toxic agents which give rise to uræmia, and one which is capable of being readily excited into the greatest activity This has been so long, and so well known, and so generally taken advantage of, that nothing seems necessary to be added in the way of lending force to the fact Something may however be suggested here, as to the most appropriate agents to be employed in special cases Elaterium has been the favorite agent employed heretofore, for the purpose of bringing about copious watery stools, and, in many respects it is admirably adapted for the purposes under consideration Not infrequently however, elaterium produces sharp irritation in the intestinal mucous tract, so much so that under some circumstances we hesitate to give it Unfortunately, also, in many renal diseases (most) leading to uræmia, the bowels are more or less the subject of irritation already existing Under such circumstances, it is desirable to use intestinal eliminants, which, while efficient in action, will not violently agravate existing irritation In such cases I have found the administration of the concentrated saline solutions, as recommended by Professor Mathew Hay, to meet the requirements quite satisfactorily Dr Hay found on investigating the action of salines, such as magnesia sulphate, and Rochelle salts, that if given in very concentrated solution, they bring away enormous quantities of fluid from the intestines, attended by but little intestinal irritation, and systemic disturbance The amount of drain from the blood of aqueous elements is very decided, carrying with it in solution the toxic agents productive of uræmia This drain is of course made good through ingoing fluids into the vessels, to equalize the volume of the blood, and hence that fluid is unloaded of much of the excrementitious waste contained therein The best results are obtained from the administration of half, to an ounce of magnesia sulphate, in about two ounces of water, given in the morning, after permitting no fluids to be taken during the night, nor must water or fluids be drank for a few hours after, lest they dilute the saline in the intestines, and defeat its action Dr Hay originally proposed this as a method of rapidly reducing dropsy, and local serous effusions, and I can testify to its efficiency in such cases also

There is one danger which it is well to have regard to in all eliminative treatment of uræmia under certain conditions, especially that of dropsy It is said that considerable quantities of those toxic agents become stored up in the dropsical fluids in the great cavities, and cellular tissues of the body, and that if the dropsy is rapidly reduced, through purgation, or other eliminative means, the toxic matters thus stored up are thrown suddenly into the circulation, and are liable thus to precipitate convulsions, or coma Dr Ralfe believes that this danger exists from the use of eliminants, even when dropsy is not present, owing to the concentration of the blood induced by their action I know of but one way to combat, or to lessen this danger, and that is to keep the blood diluted by copious draughts of water, while the eliminative measures are being carried out, and I believe this to be a very important consideration in such cases

COCAINE IN DENTAL SURGERY[1]

BY JOHN S MARSHALL, M D,

OF CHICAGO ILL

The hydrochlorate of cocaine, like all new remedies which have promised to mitigate the sufferings of mankind, was hailed with enthusiasm, and in certain lines of practice it is already gaining a firm foothold as a local anæsthetic, principally in ophthalmology and in many operations upon mucous and serous tissues On the other hand, the subject has lost much of its interest to dental surgeons from the fact that it has proved a disappointment where it was hoped that it would be of the greatest benefit, viz as an anæsthetic or obtunder of sensitive dentine And now that the enthusiasm over the drug has waned, and we begin to investigate its claims with cooler heads and less biased judgment, many of the published accounts of its wonderful effects upon sensitive dentine and the other tissues of the teeth it would seem must have originated very largely in the imagination of the writers rather than that they were clinical facts

New forms of the drug have, however, been more recently introduced which promise better results, and my excuse for presenting this paper is to call your attention to the citrate of cocaine by presenting the results of a series of experiments made with the hydrochlorate, the oleate, and the citrate, leaving you to judge which promises to be of the greatest benefit as a local anæsthetic or obtunder of sensitive dentine For operations upon mucous tissues there seems to be but little difference between any of these forms, but upon sensitive dentine and pulp tissue it will be seen that the citrate in my hands proved much more satisfactory than either of the others

To illustrate the effects of these three forms I have chosen from my records the first ten cases upon which each of these remedies was tried

The Hydrochlorate or Muriate of Cocaine —

---

[1] Read in the Section of Dental and Oral Surgery at the Thirty Sixth Annual Meeting of the American Medical Association

$C_{17}H_{21}NO_4,HCl$ contains about 88 per cent alkaloid cocaine, and is made by neutralizing the alkaloid with HCl, using as little water as possible and evaporating until crystalization takes place When this remedy was first introduced as a local anæsthetic we had great hopes of it as an obtunder of sensitive dentine, but after repeated trials with a two per cent solution, my enthusiasm cooled, for in nearly every case it was more or less a failure This I attributed to the fact that a dense tissue, like dentine, absorbs so slowly that a sufficient quantity of a two per cent solution could not be taken up to produce anæsthesia, and therefore concluded that the solutions needed to be stronger To test this I procured ten per cent and twenty per cent solutions, but was unable to get any better results with the twenty per cent than with the two per cent A forty per cent solution has also been recommended This I have not tried, but from the experience of others who have experimented with it, it seems to have no advantage over a four per cent or ten per cent solution

Case 1 —Mrs Dr D , aged 30, just recovered from her third confinement Several large cavities to fill Teeth soft and very sensitive Applied a two per cent solution of hydrochlorate of cocaine (Foucar's) to two buccal cavities extending under the gum, the inferior left first and second molars The cavities were first dried and then painted with the solution In five minutes this was repeated, and at the end of ten minutes the rubber dam was applied without pain, and the cavities excavated with so little discomfort as to call forth expressions of delight from the patient

Case 2 —Willie S , a frail boy aged 15 years, a frequent sufferer from nervous sick headache, and obliged to give up study on this account Teeth soft and exquisitely sensitive, and from his nervous condition the operation nearly unbearable Applied the two per cent solution to a large crown cavity in the inferior right second molar, after four applications at five minute intervals could obtain no appreciable effect

Case 3 —Mrs A J L , age 24 years, in good health and nursing her first child, aged 9 months Teeth of medium structure and only normally sensitive Adjusted the rubber dam to the superior left second molar and applied the two per cent solution to a distal cavity three times at five minute intervals, but at the end of twenty minutes there was no diminution of sensation

Case 4 —Mrs L , aged 24 years Applied the two per cent solution to the necks of the inferior anterior teeth and gums, these teeth being affected with pyorrhea alveolaris After two applications at five minute intervals, the gums were completely anæsthetized, and I was able to operate with very little pain At a previous sitting, without the aid of the cocaine, the operation was exceedingly painful

Case 5 —Mr L E , aged 50 years Health fair Applied Merck's ten per cent solution for the extirpation of a living pulp, the rubber dam being previously adjusted and the pulp fully exposed, but after four applications at five minute intervals there was no abatement of sensation

Case 6 —Miss Celia D , domestic aged 26 years Health good and teeth of fair structure Applied Merck's ten per cent solution three times at five minute intervals to four cavities in the inferior left bicuspids, with very slight diminution of sensitiveness

Case 7 —Dr McG , a professional friend, aged 26 years Teeth strong and dense Made three applications of Merck's ten per cent solution at five minute intervals, to two large and sensitive cavities in the superior left first molar, but could get no favorable results, on drying the cavities with the hot-air blast was able to excavate with considerable mitigation of the pain

Case 8 —Master George L , aged 14 years Health not very good, suffers from headache on the least nervous excitement Teeth very soft The application of Merck's twenty per cent solution in the same manner and at the same intervals to several sensitive cavities seemed to afford a little relief The hot air blast was also used and seemed to afford still greater relief

Case 9 —Master Charles H , aged 16 years, and in fine health Teeth medium in structure Merck's twenty per cent solution was applied, as above, to several teeth at different sittings with only a very slight abatement of the sensitiveness The hot-air blast was also used in this case upon teeth which had been treated with the twenty per cent solution, and upon teeth which had not, and the sensitiveness was lessened just as much in those teeth where the hot-air blast was used alone, as where it was used in connection with the cocaine

Case 10 —Mrs L B M , aged 24 years Health good, teeth medium in structure Applied Merck's twenty per cent solution to two very sensitive cavities four times at five minute intervals, but with no perceptible benefit

Oleate of Cocaine —$C_{17}H_{21}NO_4,C_{18}H_{33}O_2$ Normal oleate of cocaine contains from forty eight to fifty-two per cent alkaloid cocaine, and is prepared similarly to the hydrochlorate, using oleic instead of hydrochloric acid Through the kindness of McKesson and Robbins, I was able to test the efficiency of the normal oleate and the five per cent manufactured by them

Case 1 —Annie O B , dispensary patient, aged 12 years Applied five per cent oleate to the gums for the extraction of an abscessed inferior right first molar Made three applications at three minute intervals Gum lost sensation in eight minutes, and the tooth was extracted at the expiration of twelve minutes Patient said "It hurt very badly"

Case 2 —Mr K , dispensary patient, aged 40 years Applied five per cent oleate to the gums for the extraction of the root of the superior right first bicuspid, which was the seat of an abscess, and very sore to the touch Made two applications at three minute intervals At the end of seven minutes the gums had lost sensation, and at ten minutes from the first application the tooth was extracted The patient declared the pain was considerable, but not as bad as he expected

Case 3 —Mr E F , Sr , aged 60 Teeth dense Attempted to extirpate a living pulp for this gentleman from the inferior left second bicuspid Applied the five per cent oleate twice at three minute intervals, at the expiration of ten minutes there was no anæsthetic effect Made a third application, and at thirty minutes—the pulp being bathed in the oleate all this time and moisture excluded by the rubber dam—there was no appreciable anæsthetic effect Then applied the normal oleate for fifteen minutes with no better success

Case 4—Mrs T H B, aged 30 years, and in the most perfect health Teeth medium Applied five per cent oleate to a crown cavity in the inferior right wisdom tooth Made three applications at five minute intervals, slight pain on making the first application At the expiration of twenty-five minutes there was no effect

Case 5—Mrs George A, Jr, aged 28 Health not very good Teeth soft Is a frequent sufferer from nervous head ache, and exceedingly nervous about dental operations Applied five per cent oleate to a very sensitive crown cavity in the inferior left second molar The dam was adjusted and the cavity bathed with the remedy, at the end of ten minutes no effect, at twenty minutes the same, at thirty minutes still no abatement of sensitiveness The normal oleate was then applied for ten minutes with no better result (Since recording the above I have tried the citrate upon another tooth for this patient, equally as sensitive as the one just mentioned, with entire success)

Case 6—Master Joe R, aged 11 years Teeth soft and very sensitive Applied five per cent oleate in the usual way to several cavities, and followed it with the hot-air blast, but was unable to completely obtund the sensitiveness (At still other sittings of a later date have used the citrate with entire success)

Case 7—Miss Margaret M, aged 14 years Highly nervous organization Teeth of fair structure, but exceedingly sensitive Applied five per cent oleate to two cavities four times at three minute intervals, with but very slight obtunding effect

Case 8—Mrs Anna B, aged 40 years Health good Applied the five per cent oleate to the gums preparatory to fitting the band for an artificial crown, upon the root of the superior left central incisor In fifteen minutes anæsthesia of the gum was perfect, but at the border of the alveolus, sensation was still acute, this I was unable to overcome after an hour's trial

Case 9—Miss J P, aged 35 years Health much impaired from long-standing uterine trouble All the teeth affected with pyorrhea alveolaris Applied five per cent oleate twice at five minute intervals, and in fifteen minutes was able to scrape the roots of the teeth and slit open the pockets with very little pain

Case 10—Mrs E B, aged 42 years Health good, teeth dense and only normally sensitive Two applications of the five per cent oleate at ten minute intervals diminished the sensitiveness, but it was not entirely overcome

Citrate of Cocaine—$(C_1\ H\ _1 NO_4)_n\ H_3 C_6 H_5 O$ Contains about eighty one per cent of alkaloid cocaine, and is made after the same process as the other forms, except that citric acid is used This form of cocaine was first manufactured and recommended by E Merck, of Darmstadt, as likely to be most satisfactory as a local anæsthetic for sensitive dentine My attention was first called to it by a letter in the Journal of the American Medical Association, written from Wiesbaden, Dec 4, 1884, by Dr Sarah Hackett Stevenson I at once took steps to procure a sample manufactured by Merck for experimentation, but was unable to obtain it in this country Messrs McKesson & Robbins, however, kindly prepared a sample for me, and this was made into pills, each containing one-fourth grain, the excipient used being gum tragacanth dissolved in glycerine This readily dissolves on being moistened with water, and therefore makes a very convenient vehicle for its introduction into the cavity The citrate does not keep well in solution as it decomposes in three or four days My method of using it is as follows Remove all loose debris from the cavity, wash it out with tepid water and apply the rubber dam Place in the cavity one-sixteenth or one-eighth grain of the citrate (divide a pill into two or four equal parts), according to the size of the cavity, and place over it a pledget of cotton, moistened with tepid water, the excipient soon dissolves and flows over the surface of the cavity In five minutes I test the dentine, and if still sensitive make a second or third application

Case 1—Miss Eva J B, aged 26 years Health good Teeth soft and very sensitive Applied one-sixteenth grain of the citrate to a distal cavity in the superior right lateral incisor Slight stinging pain on application, this subsided in about three minutes, in five minutes the tooth felt benumbed (as described by the patient), in ten minutes the cavity was excavated without the least pain The anæsthetic effect lasted for about one hour

Case 2—Miss N E C, aged 19 years Health fine Teeth of good structure but quite sensitive Patient has a great dread of dental operations Applied one-sixteenth grain of the citrate Slight pain on coming in contact with the dentine, this soon subsided, and in five minutes the sensitiveness was considerably lessened Made a second application of one-eighth grain, which was allowed to remain ten minutes, when sensitiveness had entirely disappeared, and the operation was completed without the slightest pain

Case 3—Mrs John J, Jr, aged 35 years An exceedingly nervous patient, and more or less an invalid for the last ten years Teeth soft Applied one eighth grain of the citrate to a superficial cavity on the mesial surface of the superior right first bicuspid Dentine exquisitely sensitive to heat, cold, acids, sugar, etc, and the least touch of the excavator caused intense pain, and throws the patient into a nervous tremor Severe pain followed the application of the citrate, which did not subside until twenty minutes afterwards Made a second application of one-eighth grain ten minutes after the first In twenty minutes from the first application was able to partially excavate the cavity, a third application of one sixteenth grain was then made, and in thirty minutes from the first was able to finish the operation The patient said the tooth was still sensensitive but endurable I had tried some weeks previously to excavate a cavity, under the effect of a Merck's twenty per cent solution, but failed to obtain any favorable results with it

Case 4—Miss C E N, aged 20 years Health good Teeth of fair structure Applied one-sixteenth grain of citrate to two sensitive proximal cavities in the superior left first and second bicuspids Slight pain on application, at the end of five minutes sensitiveness was entirely overcome in both, and the operation was completed without pain

Case 5—Mrs John B, aged 30 years, in fair health Removed the remnants of the pulp in the superior right first molar, which had resisted devitalization after three applications of arsenous acid The pulp was hypersensitive in all three roots In fifteen minutes after the application of one eighth grain of citrate, was able to remove the pulp without the least pain

Case 6—Miss Alice C, aged 16 years Health good Teeth soft Suffering severe odontalgia from exposed pulp in the inferior right first molar Applied one sixteenth grain citrate for the relief of the odontalgia, in five minutes made a second application, and in ten minutes a third, each time doubling the dose, but after a full half hour there was no mitigation of the pain Dressed with oil of cloves and one eighth grain morphia sulph, with the effect of controlling the pain in about five minutes

Case 7—Mr Henry C, aged 18 years, in poor health Teeth soft and very sensitive Applied one-sixteenth grain to a buccal cavity in the inferior left second molar Severe pain followed the application, which lasted about five minutes Made a second application of one-sixteenth grain, and in fifteen minutes excavated the cavity without pain

Case 8—Miss Anna P, aged 24 years Health good Teeth of dense structure Applied one sixteenth grain each to two buccal cavities in the superior right and left second molars Slight pain on application, which lasted about three minutes In ten minutes was able to operate without pain

Case 9—Miss Sophia N, aged 23 years Health good Teeth soft Applied one-sixteenth grain each to two mesial cavities in the superior right and left central incisors Very slight stinging pain on application At the expiration of fifteen minutes dentine still sensitive, made a second application of one sixteenth grain, and in thirty minutes the dentine was still slightly sensitive at the bottom of the cavities Operated with but little pain

Case 10—Mr J C S, aged 20 years Health good Teeth dense, and only normally sensitive Applied one-sixteenth grain each to several cavities, and in each of them one application was sufficient to completely obtund the dentine in from eight to ten minutes

Since recording the above cases I have had opportunity to more thoroughly test the merits of the citrate, and as an obtunder of sensitive dentine it has in my hands fulfilled in nearly every instance all that it gave promise of doing From the cases recorded you will notice 1 That it is much more reliable when applied to sensitive dentine than either hydrochlorate or oleate Whether this is due to the special form of the drug or to its greater concentration as applied to the dentine, I am unable to say 2 That it also seems to act more promptly, whether applied to sensitive dentine, pulp tissue, or mucous membrane, than either of the other forms 3 In every case, so far, in which I have used it for obtunding sensitive dentine, the citrate causes a more or less sharp, stinging sensation, being similar to that produced by the application of spunk or bibulous paper in drying the cavity, or of mild solutions of chloride of zinc, but this passes away in from two to five minutes Why the application of the citrate should produce pain I am unable to say, unless it is caused by the rapid absorption of the fluids contained in the dentinal tubuli, as the citrate and the glycerine excipient have strong affinities for water, or possibly the citric acid is not completely neutralized Why case 5, in which the citrate was applied for the removal of a pulp, should be so successful, and the next case, in which it was used for the relief of odontalgia, should prove such an utter failure, is to me also equally unaccountable

The record of such a small number of cases, apparently successful, does not of course prove the citrate to be a perfect local anæsthetic for operations upon the teeth, but I trust they will be useful in calling attention to this form of the drug, and stimulate others to further test its merits

242 Wabash Ave

MEDICAL PROGRESS

ANATOMY AND PHYSIOLOGY

Large Doses of *Ipecacuanha in Acute Pneumonia*—Large doses of ipecacuanha in acute pneumonia were much given at the commencement of this century, its antiphlogistic and depressing action being empirically recognized Trousseau, Péter, and other well-known physicians were aware of the good effect of these large doses Verardini's observations confirm the utility of this method of giving ipecacuanha The dose ranges from 2 grammes (30 grains) to 4, 6, or even 8 grammes These doses are well borne and rarely cause sickness, the tolerance of the drug is in relation with the gravity of the pneumonia This may be caused by a paralysis of certain nerve-centres, as Finkler and Zunt have shown The action of the ipecacuanha is to cause contraction of the blood vessels and capillaries Large doses of ipecacuanha have not the same effect as emetin, the first cause pulmonary ischæmia, while the second cause marked hyperæmia—*London Med Rec*, July, 1885

MATERIA MEDICA AND THERAPEUTICS

A New Method of Employing Bromide and Iodide of Potassium—The marked repugnance which the bromide and iodide of potassium provoke in many patients, in whom they are imperiously indicated for numerous affections of a rheumatic, gouty, nervous, scrofulous, and syphilitic nature, has led to various hitherto but partially successful efforts of freeing these valuable drugs from this objection. Epileptic patients, who have to take large doses of the bromide of potassium daily, often object to this treatment on account of the gastric irritation which the remedy produces. There are even syphilitic patients who prefer the consequences of their diathesis to the ingestion of the potassium salt, for which they express an indomitable antipathy. In women especially, in whom the exhibition of bromides is so often called for, the practitioner is occasionally confronted with the necessity of abandoning a positively useful drug for the sake of the subjective inconvenience it causes in the patient. Children, when being treated with bromides for cardiac affections, likewise show their disgust of the medicine very plainly.

Though a great number of preparations containing these drugs in a syrupy vehicle have been offered to the medical public, we find that the nauseating, syrupy taste is always objected to by the patients, and that the exact regulation of the dose is rendered somewhat difficult, as the spoon is sometimes more, sometimes less, accurately filled. In the light of these facts, it must be regarded a pharmalogical acquisition that MR. POISSON, a prominent French apothecary, had the happy thought of incorporating these salts with chocolate and presenting them in the form of pastilles (lozenges), containing each 3 grains of either drug (*Le Progres Medicale*, April 4, 1885). Ease of ingestion, even for the most delicate and fastidious patients, perfect preservation (they contain butter of cacao), ready solubility, and avoidance of all gastric irritation, are the striking features of the new preparation, which, we feel convinced, will rapidly rise in favor even in this country. It would possibly be advantageous to prepare also lozenges containing a higher percentage of the salts, as large doses of the drug are occasionally to be taken. In conclusion, we beg to recall that Cl. Bernard has long intimated that the absorption of both bromides and iodides would be essentially facilitated by the combined addition of fatty matters and sugar. Poisson's preparation, then, appears in perfect correspondence with Cl. Bernard's prescription.—*Therap. Gazette*, June, 1885.

DESSICATED OX-BLOOD.—The old popular belief in the medicinal virtues of a blood regimen has recently been resumed with considerable enthusiasm. In Paris, as we read lately in a secular journal, there are butcher-shops exclusively devoted to the preparation and instantaneous dispensation of this rather repulsive medicine. As efficient adjuvants to this cure, baths in the same menstruum are equally *en vogue*. From theoretical grounds, there would appear little doubt that this indirect transfusion of animal blood can exert a favorable impression upon a flagging or wasting constitution, though we fail to appreciate the utility of the blood bath. It is, then, little surprising that therapeutists, in just deference to the popularity of the remedy, have subjected it to clinical trials, and, having become convinced of its therapeutic value, do not hesitate to use it, though in a somewhat modified form.

GUERDER (*Deutsche med. Zeit.*, March 17, 1885) openly advocates the systematic administration of ox-blood powder, prepared so as not to remove the salts of the blood. Fresh defibrinated blood is heated for four or five hours in a water-bath, and then slowly dried by currents of warm air, the entire preparation covering a period of at least three days.

Guerder gave this blood-powder to fifty one sick and healthy individuals, and reports that it was well borne by forty-four of them. In three instances (reconvalescence from typhoid fever) he noted vomiting, and in four others (anæmia) gastric irritation.

Children usually are ordered 2 drachms, adults 6 drachms, of the powder, to be taken at meal time in cold liquids (water, wine, milk, black coffee).—*Therap. Gazette*, June, 1885.

MEDICINE

LIPOCARDIAC ASTHMA.—Under the name of "lipocardiac asthma," PROFESSOR CANTANI gives an account of the affection described by him since 1864 as "fatty heart asthma." The patient is perhaps quiet in bed or in an arm chair, when suddenly without any apparent reason, the rhythm of his respiratory movements is disturbed. Little by little, sometimes almost insensibly, his respirations become less frequent, shorter and more profound, amounting at times to a laborious and even stertorous dyspnœa. Gradually the respirations become more frequent and profound, returning by degrees to the normal. Such attacks are usually short in duration, severe attacks last only a few minutes, and mild attacks only about two or three minutes. At first the outbreaks are unfrequent—about once a month, or three or four in the course of the year, and then they follow fatigue, muscular efforts, or emotional disturbance. As time wears on, the attacks begin to recur at short intervals and without apparent cause.

The origin of these symptoms, according to the author, lies not in mere fatty hypertrophy of the heart, but in fatty degeneration of the muscular tissue of the organ. The symptoms show themselves when the heart begins to be tired. With this muscle, however, fatigue means impossibility to continue its work with its usual power. It requires, therefore, a brief period of relative repose, of less energetic contraction. This, however, involves a less complete emptying of the ventricles. Now, during this period of relative repose, of fatigue of the heart, the quantity of blood driven into the lungs by the right ventricle and to the rest of the body from the left ventricle is, for the time, diminished. Not merely, therefore, is there less blood oxygenated in the lungs, but the blood that is oxygenated is distributed more slowly throughout the body. This insufficient supply of blood to the tissues provokes a nervous erythism, or general hyperæsthesia.

The recognition of lipocardiac asthma is important, inasmuch as the prognosis is much more unfavorable than in any other kind of cardiac asthma. It must be distinguished from angina pectoris, with which it is apt to be confounded, and with which, in fact, it is rarely conjoined. Another disorder of respiration with which it might be confounded is Cheyne Stokes' respiration. Cheyne Stokes' respiration, however, is a symptom in various morbid states. It has a different significance. In it there is apnœa, in lipocardiac asthma, on the contrary, there is only dyspnœa. Cheyne Stokes' respiration occurs at brief intervals, and does not occur long before death. Lipocardiac asthma occurs at distant intervals, and may occur for many years before death.

The treatment of lipocardiac asthma consists in improving the general health of the patient. Against the symptoms, digitalis, convallaria, valerianate of quinine, caffein, cognac, red wine boiled with cannella, etc., may be useful. In fatty persons who are not too old ferruginous preparations may be tried.—*London Med. Record*, Aug. 15, 1885.

Dilatation of the Stomach in Children.—Dr. Comby, of Lyons (*Lyon Méd.*, No. 49, 1884), regards gastric dilatation due to dietetic errors as an affection of greater frequency than commonly believed. Though appearing most frequently in children fed artificially, especially if early accustomed to solid food, it is occasionally found in nursing children, and is then to be attributed to either excess in quantity or undue richness of the milk. The most prominent symptoms of the affection are inflation of the stomach, tympanitis, and a ringing noise (*bruits de clapotage*), as also found in adults.

Occasionally we find alongside of dyspeptic troubles nervous symptoms, such as convulsions, insomnia, and sometimes eczema and impetigo. Comby refers also to the coincidence of this affection with rachitis, though without regarding it as a rachitic symptom.

The prognosis is to be guarded, as the affection sometimes extends to puberty, and even longer. The treatment is to be of an exclusively dietetic nature. Artificial food is to be excluded, improper articles of diet to be banished, the weaning to be delayed, and strict general surveillance to be enforced. Washing out the stomach has, in some instances, proved advantageous.—*Therap. Gazette*, June, 1885.

Lactic Acid in Laryngeal Tuberculosis.—Dr. H. Krause, in following up the experimental application of lactic acid as pointed out by Mosetig-Moorhof, who has found its valuable in the local treatment of fungous caries, lupus vulgaris, superficial epithelioma, and papilloma, has made use of the remedy in the local treatment of laryngeal tuberculosis. The cases which he records had previously been under treatment, and a great variety of agents was used without beneficial result. Among the remedies used were iodoformized glycerine, boric acid, carbolic acid, and creasote either with morphia or cocaine.

The cases in which the pathological condition was treated are fourteen in number, and microscopic examination showed the presence of the bacillus tuberculosis in every instance. The results of the local application of the lactic acid were as follows: Hand in hand with the decrease of the infiltration and the scar of the ulcer a diminution of pain was noticed, and at the same time diminution of the secretion. The subjective result so far as the larynx is concerned is, that in all the patients, without exception, the condition was markedly improved.

Concerning the return and persistence of the cure after cessation of treatment nothing can be reported on account of the limited time covered by the observations. Dr. Krause considers, however, that the use of the acid is of certain efficacy in the treatment of this form of tuberculosis, and especially worthy of trial in the light of the failure hitherto experienced in the treatment of this affection of the larynx.

Even in cases in which, owing to far advanced pulmonary tuberculosis, and the general effects of the disease, only a most unfavorable prognosis could be given, the dysphagia accompanying the disease was much diminished by lessening perichondrial œdematous infiltration. The writer further does not hesitate to express a hope that in the least unfavorable cases in which laryngeal tuberculosis has not advanced too far, and the general constitution is well conserved, the use of lactic acid will render it possible to destroy the infiltrated tissue and effect the concurrent cure of the local process. The writer, in conclusion, also suggests the application of lactic acid in other diseases of the mucous membrane of the upper air-passages, among which may be mentioned the diffused swelling and circumscribed thickening accompanying chronic nasal pharyngeal and laryngeal catarrh.—*Berliner klin. Wochenschr.*, July 21, 1885.—*Medical News*, Aug. 22, 1885.

Glycerine as a Prophylactic against Trichinosis.—In the *Archiv für Kl. Med.*, Bd. 36, 1885, is a very striking illustration of the prophylactic value of glycerine against trichinosis, which, though denied by Fiedler, has been previously upheld by Heller (*Riemssen's Hanb. d. Pathol. u. Ther.*, Bd. iii, S. 404).

A travelling merchant, who had taken some ham with him from home, was suddenly advised by a telegram that the ham contained trichinæ, which was positively verified by a physician to whom he presented the ham for examination. Having, however, previously eaten of the ham, he entered a hospital for treatment. His diet was restricted to a minimum, and he was given first 10 ounces of infusum fol. sennæ comp. in combination (which removed some uncapsulated trichinæ), and was then placed on a glycerine treatment, a teaspoonful to be taken hourly for several days. He completely escaped all symptoms of trichinosis, while nearly all his relations at home, who had also eaten from the same ham, contracted serious illness.—*Therap. Gazette*, June, 1885.

SURGERY.

Experiments on Engrafted Bone.—Dr. Ambrogio Ferrari, after a series of experiments on the phenomena attending the engrafting of bone, draws the following conclusions:

1. Pieces of bone engrafted into the shaft of a long bone become completely united and continue to live.
2. They not only continue to live, but also grow.
3. That these results follow without reference to the position in which the engrafted bone is placed.
4. The reunion of grafts occurs by a true vascularization which takes place between the engrafted bone and that into which it is introduced.

5 That a bony callus, periosteum, and medulla are formed in relation with the engrafted bone

6 That this callus possesses a temporary vitality, as in fracture

7 That after a certain time the callus, periosteum, and medulla are absorbed, and the engrafted bone is nourished only by a greater vascularization

8 That grafting occurs more completely if the inserted bone is in exact adaptation with the margins of the bone receiving it While this observation is not verified, in a case where the opposite condition existed, a longer time was necessary for union to take place

9 The most complete and careful antisepsis is required in order that complete union of the engrafted bone may occur

10 The engrafting of several pieces of bone is completely successful

11 That in case of engrafting of several pieces of bone with partial suppuration, union of some of the pieces may take place, provided suppuration does not extend to that portion of the engrafted bone in *communication with the medulla*

12 Besides antiseptic precautions, compression is required to maintain contact between the medulla and the pieces of bone engrafted, in order to obtain a successful result —*Gazzetta degli Ospitali*, July 22, 1885

DIAGNOSIS OF CHANCRE OF THE TONSIL —DR FRANK DONALDSON, Jr , gives the diagnosis of chancre of the tonsil as follows

SYPHILIS	CANCER
Functional Symptoms	*Functional Symptoms*
Deglutition and swallowing painful, but rarely impossible, with freedom from pain when the parts are at rest	Difficulty and pain in swallowing the first and constant symptom, increasing until it is impossible to take food Lancinating pain referred to the ear
Physical Signs	*Physical Signs*
Some hypertrophy with early superficial ulceration in primary sore The tertiary ulcer perforating and cone shaped Comparatively slight glandular enlargement, not painful, and subsides with the cause of the irritation	Great hypertrophy, later wide spread ulceration Considerable glandular enlargement and induration, which become very painful, and do not disappear
Hemorrhage rare	Hemorrhage frequent
Slight emaciation	Great emaciation
Amenable to treatment	Not cured by any treatment

Tonsil chancre may, under some circumstances, be taken for a mucous patch, whose favorite seat would seem to be upon the surface of the tonsil, and this is more likely to happen when the patient is seen for the first time, and secondary symptoms have already manifested themselves, and an ulcer still remains upon the tonsil, or when there is hypertrophy of the tonsil, with an active, and by no means superficial, ulceration of the mucous patch The mucous patch, however, always follows the roseola, and the patch is, as a rule, superficial and of characteristic appearance, etc To determine finally between a chancre and a mucous patch upon the tonsil Diday says "Cauterize the ulcer twice at an interval of five days, and if it is a secondary ulcer, it will disappear, if a primary, hard chancre, it will not"

In exceptional cases chancre of the tonsil is complicated by an extensive slough The presence of a grayish ulcer, surrounded by an œdematous circle, with inflammation of the surrounding parts, points strongly to a gangrenous throat affection, either of a syphilitic origin or a primary gangrenous angina, such as is described by Gubler and Trousseau The limitation of the ecchymotic spots, and the absence of its propagation to the pharynx, palate, and larynx, and the general course of the affection, with the appearance or non appearance of secondary eruption, will settle the diagnosis

Ulcerating, gummy tumor of the tonsil is distinguished from chancre by a deeper ulceration, and by its dug-out edges According to Legendre, a good differential sign is the existence of an erythema and peripheral engorgement, which are never found in gummy tumors, but always present in throat chancre Further, a knowledge of the patient's antecedents will be of great value

Finally if the lesion upon the tonsil has been of slow unilateral development, is superficial, with grayish white deposit, if there is a history, or even suspicion of syphilitic exposure, if there is glandular enlargement, if the sore on the tonsil appeared from fifteen days to three weeks after exposure, and there is absence of chancre elsewhere, if the patient has not been subject to simple tonsillar angina, if the pain is on the affected side, has lasted for some days or weeks, and has not excited febrile reaction, and the whole is followed in due time by an outbreak of secondary symptoms, certainly we are justified in a diagnosis of chancre of the tonsil —*Medical News*, Aug 15, 1885

PEAT-MOSS AS A DRESSING —In the *Vratch*, No 24, 1885, p 389, DR VASILY E NESHEL, of the Obukhovsky Hospital, in St Petersburg, drawn attention to dry peat-moss as an excellent and cheap absorbent and dressing material, and fully endorses the statements of Leisrink (who first began to use it), Mielk, Korach, Hagedorn, and Schede It costs only 50 copeks per *pud* (about one shilling per 16 3 kilogrammes), may be gathered everywhere, and does not require any other previous treatment except picking out any foreign admixture (such as small twigs, leaves, etc), occasional moistening with a solution of corrosive sublimate, and drying Peat-moss in employed in the share of gauze bags or pads of various sizes The wound is covered first with a piece of iodoform gauze, then with a layer of sublimatised gauze, and over the latter a gauze bag filled with moss and slightly moistened with a carbolic or sublimatised solution, is laid, the whole being kept in place by a roll bandage Wounds remain perfectly dry under a moss bag The latter is found to be odorless six, eight, and more days, even in presence of very profuse purulent discharge Any fluid absorbed by moss rapidly evaporates To prevent overdrying, it is advisable from time to time to moisten the moss bag lying on the wound with an antiseptic solution —*London Med Rec* , Aug 15, 1885

THE
Journal of the American Medical Association
PUBLISHED WEEKLY

The Editor of this Journal would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published All communications in regard to editorial work should be addressed to the Editor

SUBCUTANEOUS SECTION OF THE LIGAMENTS IN CLUB FOOT

In September, 1882, M Jules Guerin presented to the Académie de Médecine a short note on "Partial or Total Ablation of the Tarsal and Metatarsal Bones in the Treatment of Congenital Club Foot,' and most surgeons will remember the fierce discussion to which it gave rise at the time, some claiming that the proposed operation offered only an infirmity for a deformity Nevertheless, some of the Academicians upheld him in his claim that the operation might be very beneficial in the cases in which he thought it indicated

M Guérin again brought up the subject at the meeting of the Académie on August 18, calling attention to the fact that in those cases which, on account of great deformity, age, or complexity, resist the ordinary means of subcutaneous tenotomy, manipulations and apparatus, there is a fourth means which may entirely correct the trouble This consists in subcutaneous section of the ligaments of the foot (tarso metatarsal), or, as he terms it, syndesmotomy

The ligaments to be divided in these cases are the inferior calcaneo cuboid ligament in extreme plantar equinus, in irreducible varus equinus, the internal lateral ligament of the tibio-tarsal articulation, the internal calcaneo scaphoid, and the ligaments uniting the scaphoid and cuneiform bones Guérin claims that with this complementary operation he has not seen a single case of club foot in more than a thousand which was not remediable—the other means being of course used after the operation The danger from the operation is very slight, and if proper precautions be taken to avoid the blood-vessels and nerves there is, we may say, no danger The wound always cicatrizes immediately, and without suppuration At the same time, there are certain precautions which should be adopted, in the way of making the incision at some distance from the ligament to be divided, and, if possible, at the base of a fold of the of the skin, closing the wound after the blood and other fluids have been carefully removed, and abstaining from efforts at redressment until cicatrization has taken place, and then only to make the manipulations gradually and slowly

This operation was first brought before the profession by M Guérin in 1840, and it would seem that his successes with it since that time would be sufficient evidence of its value In October, 1884, he operated on a case of extreme equino-varus, for which an ineffectual operation had been performed five years previously, when the patient was nine years old He divided the tendo Achillis in two places, above and below the old cicatrix, both tibial tendons, the tendon of the abductor pollicis, and then divided the internal lateral ligament, and the calcaneo-scaphoid and scaphoido cuboidean ligaments The operation was a complete success in every respect

In the discussion which followed, M Bouley said that he had been astonished that this operation was not more often performed, and he thought it unquestionable that it was a most useful complementary operation to the orthopædic surgery of the foot

ORGANIZATION OF THE NINTH INTERNATIONAL CONGRESS

In another part of the present number of the Journal, will be found so much of the proceedings of the Committee of Arrangements at its meeting in New York, on the 3d and 4th inst, as relates to the rules finally adopted for the preliminary organization and government of the Congress, including the General Officers, the Presidents of the Sections, and the Executive Committee, to which is committed all further management of the affairs of the Congress

It will be seen that the first rule opens the doors of the Congress to all members of the regular profession of medicine in this and other countries, with no restrictions other than the simple inscription of their names on the register, and taking out of tickets of admission That the General Officers selected and the Presidents of Sections, are not only men of eminence in the different departments of medicine in this country, but also fairly representative of the profession of the United States, as distinguished from a few chief centres, must be admitted by all candid or unprejudiced men That they collectively constitute an Executive Committee to which can be safely entrusted the entire management of the Congress, there can be no question, yet authority is given to add a limited number of such eminent men as may be found willing to give their personal assistance in carrying on the important work devolved upon the Committee under the rules now adopted

May we not hope, therefore, that a spirit of harmony will be fostered, and that all who hold the honor and interests of the profession above all personal considerations will cease to discuss the past, and cordially co-operate in making the International Congress of 1887 an honor to our country and a benefit to the profession of the world

SHOULD ARSENIC BE ADMINISTERED TO NURSING WOMEN?

At a recent meeting of the Société de Medecine Légale, in Paris, M Brouardel reported a very interesting case bearing upon this question He was called upon to say whether an infant of twelve months could be poisoned by the milk of its mother when she had taken a considerable quantity of arsenic

In the case in question, a man who had had some trouble with his wife and mother in-law was suspected of having given arsenic to them Both were made ill, and the child died with symptoms of cholerine a few days afterwards As the weather was quite warm, however, it was not suspected that the death of the child was due to any other cause than a severe case of summer diarrhœa But when the wife and mother-in-law were again attacked, with the same severe symptoms, in November, the husband was suspected, and the wife claimed to have found a package containing a white powder in her husband's pocket

The case being then submitted to Brouardel, he exhumed the body of the child, which had been buried six months previously It was completely transformed into adipocere, so that it was impossible to separate the viscera from the other parts It was therefore subjected to analysis *en bloc* It weighed about 2 50 kilogrammes, and contained 5 milligrammes of arsenic It was impossible that this arsenic could have been derived from the cloths enveloping the cadaver or from the soil in the vicinity of the grave

The next question was to determine whether arsenic is eliminated by the milk, and in what proportions M Gabriel Bouchet, for this purpose, administered Fowler's solution, in doses of gtt ij—xij, to a number of the wet-nurses, and found that the milk afterwards contained a proportionately large quantity of arsenic When, for example, the woman had taken 8 milligrammes of arsenic for six days, 100 grammes of milk contained 1 milligramme of arsenic With these doses of Fowler's solution neither the nurses nor the children felt any bad effects from the experiments In order to determine whether the effects would have been the same had the arsenic been administered in one large dose, experiments were made on animals The results were not very conclusive, however, as the susceptibility of animals to arsenic is very variable But it was conclusively shown that arsenic is constantly eliminated by the lacteal glands, whence it seems that it should not be administered to nursing women—or only with the greatest care

From a medico legal point of view it is interesting to note that Brouardel reported to the court that the body of the infant contained a quantity of arsenic sufficient to have caused the death of a child one year old, and that this arsenic could have entered the body of the child only through the mother's milk There was no defense, and the husband was sentenced to twenty years imprisonment at hard labor

REPORT OF THE COMMITTEE APPOINTED TO ARRANGE FOR THE MEETING OF THE INTERNATIONAL MEDICAL CONGRESS IN AMERICA, IN 1887

At the regular annual meeting of the American Medical Association, held in New Orleans, in April, 1885, the following resolutions were adopted

1 "*Resolved*, That the Committee appointed by this Association, to arrange for the meeting of the International Medical Congress in America, in 1887, be enlarged by the addition of thirty eight members, one from each State and Territory, the District of Columbia the Army, Navy, and Marine Hospital Service, to be appointed by the Chairman at this meeting, and that the Committee, thus enlarged, shall proceed at once to review, alter, and amend the motions of the present Committee as it may deem best"

(This resolution was amended by the provision, "that the members of the Committee should be selected by the respective State delegations")

2 "*Resolved*, That the Committee appointed in pursuance of a resolution adopted by this Association, April 30, 1885, to constitute an addition to the original Committee of eight previously appointed to invite and make arrangements for the meeting of the International Medical Congress, to be held in Washington, D C, in 1887, be, and the said Committee is, hereby authorized and empowered to select a Chairman and a Secretary, and to fill all vacancies that may occur by death or inability to attend in the Committee, and to appoint the officers of the Congress"

The following is a list of the Committee enlarged in accordance with the first resolution as amended

At an informal meeting of the Committee, held at New Orleans during the session of the American Medical Association, in April, 1885, Dr R Beverly Cole, of San Francisco, Cal , was elected temporary Chairman, and Dr John V Shoemaker, of Philadelphia, Pa , was elected temporary Secretary

The Committee held its first regular meeting at Chicago, Ill , on June 24th and June 25th, 1885, for the purposes of organization and the transaction of the business committed to it by the American Medical Association

In order to facilitate the holding of meetings in different sections of the country, the Committee deemed it advisable to select a Vice Chairman, in addition to a Chairman and a Secretary

The following named members were present at the meeting held in Chicago

G Baird, M D , Wheeling, W Va
Robert Battey, M D , Rome, Ga
F W Beard, M D , Vincennes, Ind
*J S Billings, M D , Washington, D C
R Beverly Cole, M D , San Francisco, Cal

N F Essig, M D , Plattsburg, Mo
G F French, M D , Minneapolis, Minn
A Y P Garnett, M D , Washington, D C
John B Hamilton, M D , Washington, D C
*I M Hays, M D , Philadelphia, Pa
George A Ketchum, M D , Mobile, Ala
D A Linthicum, M D , Helena, Ark
John L Lynch, M D , Baltimore Md
J W McLaughlin, M D , Austin, Texas
X C Scott, M D , Cleveland, O
*Nicholas Senn, M D , Milwaukee, Wis
John V Shoemaker, M D , Philadelphia, Pa
F L Sim, M D , Memphis, Tenn
A R Smart, M D , Hudson, Mich
D W Stormont, M D , Topeka, Kan
E F Upham, M D , West Randolph, N Y
W H Wathen, M D , Louisville, Ky
W Watson, M D , Dubuque, Iowa
A H Wilson, M D , Boston, Mass

The resignation of Dr Austin Flint, of New York, as a member of the Committee, was presented and accepted Dr J W S Gouley, of New York, was elected to fill the vacancy, and took his seat with the Committee

The Committee then organized, a majority of its members being present, by the election of the following officers

Chairman, Dr R Beverly Cole, San Francisco Cal
Vice-Chairman, Dr John S Lynch, Baltimore, Md
Secretary, Dr John V Shoemaker, Philadelphia, Pa

After the organization of the Committee, the number of members necessary for a quorum for future meetings was fixed at fifteen

The following preamble and resolution were adopted, to apply to future meetings of the Committee

> "*Whereas* —It is expedient that the meetings of this Committee shall represent, as far as practicable, the profession of all portions of our country
>
> "*Resolved* —That any member of this Committee who may be unable to attend a meeting, shall be empowered to send as his proxy for the meeting any member of the American Medical Association, in good professional standing and a resident of his State or a member of his Government Department "

In the course of the meeting in Chicago, on June 24th, and 25th, 1885, a plan of organization of the Congress was adopted, certain officers of the Congress were appointed, in accordance with the instruclectively constitute an Executive Committee to which can be safely entrusted the entire management of the Congress, there can be no question, yet authority is given to add a limited number of such eminent men as may be found willing to give their personal assistance in carrying on the important work devolved upon the Committee under the rules now adopted

---

*Resigned

*Resigned

May we not hope, therefore, that a spirit of harmony will be fostered, and that all who hold the honor and interests of the profession above all personal considerations will cease to discuss the past, and cordially co-operate in making the International Congress of 1887 an honor to our country and a benefit to the profession of the world

SHOULD ARSENIC BE ADMINISTERED TO NURSING WOMEN?

At a recent meeting of the Société de Medecine Légale, in Paris, M BROUARDEL reported a very interesting case bearing upon this question He was called upon to say whether an infant of twelve months could be poisoned by the milk of its mother when she had taken a considerable quantity of arsenic

The revised rules for the organization of the Congress and a revised list of officers will be presented with this report

In August, 1885, the Chairman, the Vice Chairman, and the Secretary, after consultation and communication with members, called a meeting of the Committee, to be held in New York City, September 3d, 1885, for the purposes of revision of the rules and the filling of certain vacancies in the list of officers of the Congress

The Committee met in New York City, September 3d, 1885, the following named members being present

Dr G Baird
" Robert Battey
" L P Bush
" R Beverly Cole
" W C Dabney
" Ellsworth Eliot
" A Y P Garnett
" S C Gordon
" J W S Gouley
" J B Hamilton
" George A Ketchum
" R A Kinloch
" D A Linthicum

Dr John S Lynch
" R C Moore
" William Pierson
" N J Pitman
" L A Sayre
" X C Scott
" John V Shoemaker
" F L Sim
" E F Upham
" W H Wathen
" W C Wile
" A H Wilson

The following named members were represented by proxies

Dr E P Cook, by Dr N S Davis, proxy
Dr A R Smart, by Dr William Brodie, proxy
Dr J M Taylor, by Dr E P Sale, proxy

The Committee was called to order at 12 M, September 3d, 1885, by the Chairman, Dr R Beverly Cole

The resignation of Dr L A Sayre, of New York, as member of the Committee, was received and accepted, and Dr A Flint, Jr, of New York, was elected to fill the vacancy and took his seat with the Committee The resignation of Dr Sayre was caused solely by ill health

The following "Rules" were unanimously adopted

RULES

1 The Congress shall consist of members of the regular profession of medicine, and of such other scientific men as the Executive Committee of the Congress may see fit to admit, who shall have inscribed their names on the register and shall have taken out their tickets of admission

2 The dues for members of the Congress shall be ten dollars each for members residing in the United States

There shall be no dues for members residing in foreign countries

Each member of the Congress shall be entitled to receive a copy of the "Transactions" for 1887

3 The Congress shall be divided as follows, into seventeen Sections

I General Medicine
II General Surgery
III Military and Naval Surgery
IV Obstetrics
V Gynæcology
VI Therapeutics and Materia Medica
VII Anatomy
VIII Physiology
IX Pathology
X Diseases of Children
XI Ophthalmology
XII Otology and Laryngology
XIII Dermatology and Syphilis
XIV Public and International Hygiene
XV Collective Investigation, Nomenclature, Vital Statistics, and Climatology
XVI Psychological Medicine and Diseases of the Nervous System
XVII Dental and Oral Surgery

4 The General Meetings of the Congress shall be for the transaction of business and for addresses and communications of general scientific interest

5 Questions and topics that have been agreed upon for discussion in the Sections shall be introduced by members previously designated by the titular Officers of each Section Members who shall have been appointed to open discussions shall present in advance statements of the conclusions which they have formed as a basis for debate

6 Brief abstracts of papers to be read in the Sections shall be sent to the Secretaries of the proper Sections on or before April 30, 1887 These abstracts shall be treated as confidential communications, and shall not be published before the meeting of the Congress

Papers relating to topics not included in the lists of subjects proposed by the Officers of the Sections may be accepted after April 30, 1887, and any member wishing to introduce a topic not on the regular lists of subjects for discussion shall give notice of the same to the Secretary General, at least twenty one days before the opening of the Congress, and such notices shall be promptly transmitted by the Secretary-General to the Presidents of the proper Sections The titular officers of each Section shall decide as to the acceptance of such proposed communications and the time for their presentation

7 All formal addresses, scientific communications and papers presented, and scientific discussions held at the General Meetings of the Congress, shall be promptly given in writing to the Secretary-General, and all papers presented and discussions held at the meetings of the Sections shall be promptly given in writing to the Secretaries of the proper Sections

No communication shall be received which has already been published, or read before a society

The Executive Committee, after the final adjournment of the Congress, shall direct the editing and the publication of its "Transactions," and shall have full power to publish the papers presented and the discussions held thereon, either in full, in part, or in abstract, as in the judgment of the Committee may be deemed best

8 The official languages of the Congress shall be English, French, and German

In the meetings of the Sections, no member shall be allowed to speak for more than ten minutes, with the exceptions of the readers of papers and those who introduce subjects for discussion, who may each occupy twenty minutes

9 The rules and programmes shall be published in English, French, and German

Each paper and address shall be printed in the "Transactions" in the language in which it was presented, and preliminary abstracts of papers and addresses also shall be printed, each in the language in which it is to be delivered

All discussions shall be printed in English

10 The President of the Congress, the Secretary-General, the Treasurer, the Chairman of the Finance Committee, and the Presidents of the Sections, shall together constitute an Executive Committee of the Congress, which Committee shall direct the business of the Congress, shall authorize all expenditures for the immediate purposes of the Congress, shall supervise and audit the accounts of the Treasurer, and shall fill all vacancies in the offices of the Congress and of the Sections This Committee shall have power to add to its membership, but the total number of members shall not exceed thirty A number equal to one-third of the members of the Committee shall constitute a quorum for the transaction of business

11 The Officers of the Congress shall be a President, Vice-Presidents, a Secretary-General, four Associate Secretaries, one of whom shall be the French Secretary, and one of whom shall be the German Secretary, a Treasurer, and the Chairman of the Finance Committee

12 The officers of each Section shall be a President, Vice-Presidents, Secretaries, and a Council

13 The officers of the Congress and the officers of the Sections shall be nominated to the Congress at the opening of its first session

14 The Executive Committee shall, at some convenient time before the meeting of the Congress, prepare a list of foreign Vice Presidents of the Congress and foreign Vice Presidents of the Sections, to be nominated to the Congress at the opening of its first session

15 There shall be a standing Committee on Finance, composed of one representative from each State and Territory, the District of Columbia, the Medical Department of the Army, the Medical Department of the Navy, and the Marine Hospital Service

The Chairman of the Finance Committee shall report to the Executive Committee of the Congress

Each member of the Finance Committee shall appoint a local Finance Committee for his State, Territory, District, or Government Department, consisting of one or more members from each Government Department or Congressional District

Each local Finance Committee shall report through its Chairman to the Chairman of the Finance Committee of the Congress

Dr S C Gordon, of Maine, recalled his withdrawal from the Congress, which action was accepted by the Committee

The following named gentlemen were elected to fill vacancies in the Committee of Arrangements

Dr J K Bartlett, Wisconsin
Dr J H Baxter, U S Army
Dr George Goodfellow, Arizona
Dr Henry Leffman, Pennsylvania
Dr John Morris, Maryland
Dr J R Tipton, New Mexico
Dr Thomas J Turner, U S Navy

The following resolution was adopted

Resolved, That the representative or representatives in this Committee from each State, Territory, or Government Department, shall organize the Financial Committees in their respective States, Territories, or Government Departments

It was decided that no person should occupy more than one position in the organization of the Congress

It was also decided that, in the published lists of the Officers of the Congress, the names of the Vice-Presidents and Secretaries of the Congress, and the Vice-Presidents, Secretaries and members of Councils of the Sections, should be arranged alphabetically.

OFFICERS OF THE CONGRESS

PRESIDENT

Austin Flint, M D , LL D , New York

VICE-PRESIDENTS

W O Baldwin, M D , Alabama
H I Bowditch, M D , Massachusetts
William Brodie, M D , Michigan
Henry F Campbell, M D , Georgia
W W Dawson, M D , Ohio
R Palmer Howard, M D , Canada
E M Moore, M D , New York
Tobias G Richardson, M D , Louisiana
Lewis A Sayre, M D , New York
J M Toner, M D , District of Columbia.
The President of the American Medical Association
The Surgeon General of the United States Army.
The Surgeon-General of the United States Navy
The Supervising Surgeon-General of the United States Marine Hospital Service

SECRETARY-GENERAL

Nathan S Davis, M D , LL D , Illinois

TREASURER

E S F Arnold, M D , M R C S , New York

CHAIRMAN OF THE FINANCE COMMITTEE

Frederick S Dennis, M D , M R C S , New York

EXECUTIVE COMMITTEE OF THE CONGRESS

Austin Flint, M D , LL D , President of the Congress
Nathan S Davis, M D , LL D , Secretary-General.
E S F Arnold, M D , M R C S , Treasurer
Frederick S Dennis, M D , M R C S , Chairman of the Finance Committee

PRESIDENTS OF THE SECTIONS

A B Arnold, M D , General Medicine
William T Briggs, M D , General Surgery
Henry F Smith, M D , Military and Naval Surgery.
DeLaskie Miller, M D , Obstetrics
Robert Battey, M D , Gynæcology
F H Tirrell, M.D , Therapeutics and Materia Medica

William H Pancost M D , Anatomy
John C Dalton, M D , Physiology
E O Shakespeare, M D , Pathology
J Lewis Smith, M D , Diseases of Children
A W Calhoun, M D , Ophthalmology
S J Jones, M D , Otology and Laryngology
A R Robinson, M D , Dermatology and Syphilis
Joseph Jones, M D , Public and International Hygiene
Henry O Marcy, M D , Collective Investigation, Vital Statistics and Climatology
John P Gray, M D , LL D , Psychological Medicine
Jonathan Tafft, M D , Dental and Oral Surgery

LOCAL COMMITTEE OF ARRANGEMENTS
(With power to increase their number)

A Y P Garnett, M D , Chairman, District of Columbia
The Surgeon-General U S Army
The Surgeon General U S Navy
The Supervising Surgeon General U S Marine Hospital Service
J H Baxter, M D , District of Columbia
C H A Kleinschmidt, M D District of Columbia
N S Lincoln, M D , District of Columbia
J M Toner, M D , District of Columbia,
and such additional members of the profession in the District of Columbia as the Executive Committee of the Congress may select

Lists of Vice-Presidents, Secretaries, and Councilmen for each Section were named by the Committee of Arrangements, but as it was not practicable to ascertain at once who would accept the places assigned them, or who of those who had been announced in the medical press as declining to accept positions before the present rules and organization had been adopted, as given heretofore, might wish to withdraw such declination, the final adjustment of these offices was referred to the Executive Committee of the Congress, and all correspondence in relation thereto was transferred to the Secretary General of the Congress

On motion, the Committee of Arrangements adjourned, subject to the call of the Chairman of the Committee JOHN V SHOEMAKER,
Secretary of the Committee of Arrangements

SOCIETY PROCEEDINGS

AMERICAN DERMATOLOGICAL ASSOCIATION

(*Concluded from page 684*)

WEDNESDAY, AUGUST 26—EVENING SESSION

Dr J NEVINS HYDE, of Chicago, read a paper on

THE RELATIONS OF LUPUS VULGARIS TO TUBERCULOSIS

He began with a detailed statement of all the cases of lupus reported to the Statistical Committee of the American Dermatological Association during the last seven years, and compared the frequency of the disease in this country with that reported in the Vienna Hospitals He then gave details of twenty consecutive cases observed by him in Chicago The clinical deductions from these records were then added, showing, according to the author, that there was a remarkable absence of pulmonary tuberculosis, scrofula and allied diseases in the family histories of the last twenty cases reported

The teachings of the two schools, represented in the past by prominent German and French authors were then referred to, and finally the later investigations demonstrating that lupus vulgaris was the result of bacillus infection, not to be differentiated in external appearance of the parasite from the bacillus tuberculosis

The following clinical facts were then cited in support of the later teaching of this subject as bearing on the vital point in the author's argument, viz , that lupus vulgaris was not the result as had long been taught of tuberculosis or other systemic diathesis, but was the product of a local infection by bacilli, entirely unassociated with any constitutional evidence of diathesis or predisposition 1 The unimpeachable character of the family record in by far the larger number of cases of lupus vulgaris 2 The fact that the disease is in its inception a disorder of the period of childhood, when for the most part, the habits of the child are favorable to infection 3 The several sites of predilection are those most favorable to such infection 4 The failure of the disease to spread by inheritance 5 The remarkable tendency of lupus vulgaris to cutaneous limitation

DR J C WHITE, of Boston, read a paper on

THE TREATMENT OF LUPUS BY PARASITICIDES

He briefly reviewed the evidence in favor of the parasitic nature of the affection All previous plans of treatment which had proved most successful, were those which would have the effect of destroying any parasite which might be present

A number of cases were then reported in which the local use of corrosive sublimate in the strength of two grains to the ounce of water or unguent had been used with beneficial results The ointment was especially recommended It had been rarely necessary to prolong treatment over two months As regards the permancy of the cure, the author was unable to speak, as the experiments had been continued for only eighteen months

DR S SHERWELL, of Brooklyn, expressed his profound disbelief in the parasitic nature of the disease, and did not think that the theories of Koch had been entirely proved It seemed to him that lupus and the scrofulous diatheses represent some form of syphilitic hereditary influence

DR S WIGGLESWORTH, of Boston, suggested that the oleates might be more efficient than ointments, on account of their penetrating power

Dr HYDE said that at the last meeting of the Association, Dr Taylor suggested the use of a solution of corrosive sublimate in tincture of benzoin He had used this in cases of lupus and in cases of infecting chancre It makes an excellent application

Dr W A Hardaway then read a paper on

THE TREATMENT OF PORT-WINE MARKS BY ELECTROLYSIS

In the treatment of this affection, the object is to excite sufficient inflammation to cause occlusion of the vessels Electrolysis seems to be the most convenient way of doing this At first the speaker had used a bundle of needles, but he now employed only the single needle It is important to allow a period of some weeks to elapse between the applications The histories of three cases were given in which this method had been employed

Dr J C White had used this method in one case, and had obtained considerable improvement

Dr Fox thought that all admitted that spider cancers and telengiectasis are amenable to treatment of different kinds, but when we come to port wine marks, a difference is found Better results can be obtained by electrolysis than by other measures, but it does not remove the trouble entirely He had sometimes passed the electrolytic needle deeply, endeavored to strike the artery of supply, and sometimes had produced a decided effect

Dr Denslow recently had seen a case of port wine mark on the labia majora of an infant This had ulcerated when the child was brought to him As a temporary measure, he applied the liquor gutta percha In two days, without other treatment, the whole mark sloughed out, leaving nothing but a simple ulcer, which completely healed in the course of three weeks

Dr Hardaway said that the advantage of the electrolysis is that it is manageable A practical point might be referred to, and that is, if after the operation the part be frequently mopped with hot water, the inflammatory disturbance will be greatly lessened

Dr S Sherwell, of Brooklyn, then read some

REMARKS ON A MOOT POINT IN THE ETIOLOGY OF PSORIASIS

He said that he had been struck by the great diversity of opinion in regard to the general health of those affected with psoriasis, and in order to arrive at something like a consensus of opinion on the subject, he had referred to the writings of most of the authorities in dermatological matters Brief extracts from various writers were then given The evidence thus obtained, strengthened the Doctor's opinion that the patients with psoriasis were generally in good health He thought that the theory of Piffard, who believes that the rheumatic diathesis is a great exciting cause of psoriasis, was the most rational theory that had been advanced

---

THURSDAY, AUGUST 27—SECOND DAY

At the business meeting the following were elected

OFFICERS FOR THE ENSUING YEAR

President—Dr E Wigglesworth, of Boston, Mass
Vice Presidents—Dr I E Atkinson, of Baltimore, Md., and Dr A R Robinson, of New York, N Y
Secretary—Dr G H Tilden, of Boston, Mass
Treasurer—Dr H W Stelwagon, of Philadelphia

Dr E B Bronson, of New York, was elected to membership

The next meeting will be held at Indian Harbor Hotel, Greenwich, Ct, the last Wednesday of August, 1886

Dr G H Fox briefly described

TWO CASES OF DYSODROSIS

The first patient, for want of a better term, he classed under this heading The patient was twenty-nine years of age, and had always perspired freely Four years ago the eruption began on the palms of the hand and had persisted The soles of the feet had also been affected at one time The skin of the hands was decidedly thick and had a dark hue, and was dotted with numerous elevations of epidermis, averaging in size that of a hemp seed The patient had never seen any moisture in connection with this There had been no itching The skin never peeled off Puncture with a needle revealed no serum or fluid of any kind

The second case was that of a woman aged 45, a cook, whose general health was good The present trouble began five years ago The eruption is on the face and consists of numerous large and small vesicles containing clear fluid

Dr Robinson said that these latter cases are not infrequent, and may persist for months and years They consist of obstruction of the sweat duct in the corium They never cause inflammation around them, although sometimes they may be surrounded by a little areola as the result of pressure The symptoms which they present do not at all correspond to those of dysodrosis as described by Hutchinson and Tilbury Fox, as belonging to dysodrosis of the palms

Dr A R Robinson, of New York, reported some

MYCOLOGICAL STUDIES IN TINEA FAVOSA AND TINEA TRICHOPHYTINA

The epidermis of different persons differs in susceptibility to these parasites Children are more apt to suffer with tinea trichophytina and favus, while adults more frequently presented tinea versicolor All children are not equally susceptible In many cases of parasitic disease there is impaired vitality previous to the development of the affection

The reader then gave an account of his investigations to determine the exact anatomical seat of the parasitic diseases in question, and to determine the changes which they produced in surrounding tissues

The conclusion was that in favus the rete is not affected until the later stages, when ulceration had made its appearance The parasite confines itself more particularly to the corneous layer The parasite of tinea trichophytina in some cases passes down into the rete, while in others it does not

A number of sections were shown under the microscope, which illustrated the points brought out in the paper

Dr White asked the reader what evidence he had that in ringworm and favus a decreased vitality was necessary?

Dr Robinson thought the fact that it was exceedingly difficult to cure these affections occurring in broken down subjects, until the general health is improved, proved this point

Dr White said he could not agree with the speaker in the importance of depressed general health as a factor in the production of these diseases He had never seen any necessity for internal treatment in these cases Where the disease is superficial, it is readily removed, but where it involves skin covered with skin, it is difficult to cure Although he thought the improvement of the general condition has nothing to do with the cure of the parasitic trouble, yet it is of service in the restoration of the parts to their natural condition after the parasite has been destroyed

Dr Piffard agreed with Dr Robinson that there is a relation between the condition of the general system and the rapidity of development and the rapidity of cure

Dr Duhring had always held the view that a particular condition of the epidermis was necessary for the growth of the fungus In the majority of cases of obstinate ringworm that he had seen, had been in individuals in poor health, but there are exceptions to this rule What this peculiar condition of the skin is, has not been determined

Dr Heitzman agreed with Dr White He had seen strong, healthy persons covered from head to foot with tinea

Dr Denslow had recently seen a large number of cases of ringworm of the head and beard, but all the patients were well developed, muscular subjects These were cured without internal treatment

Dr Charles Heitzman, of New York, then read a paper on

THE STRUCTURE OF THE DERMA AND THE DEVELOPMENT OF ELASTIC TISSUE IN IT

He called attention to the fact that Prof Stricker, of Vienna, the acknowledged best microscopist of Europe, has now accepted his views concerning the life of basis substance Dr Gartner (who was present at the meeting), Stricker's assistant, has brought from Europe an electric picture microscope, by means of which these newly discovered facts can easily be demonstrated upon a screen to a large audience There are three varieties of basis structure, differing from each other in their chemical constituents, viz The glue yielding basis substance proper, producing the spindles within the bundles of so called fibrous connective tissue, the cement substance between the spindles, and the elastic substance developing along the edge of the bundles in advancing age and in some tumors All three varieties are traversed by a delicate reticulum of living matter, in connection with the protoplasmic cords that fill the interstices between the bundles in the shape of a comparatively coarse reticulum Thus it becomes intelligible that in morbid processes, not only the protoplasm, but also the basis substance, participates in an active manner After the liquifaction of the solid fields of glue-yielding basis substance, the bundles directly are transformed into inflammatory corpuscles, from which starts every physiological and pathological new formation

Dr W A Hardaway described

A CASE OF MULTIPLE MYOMATA OF THE SKIN, ACCOMPANIED WITH SEVERE PAIN

A B, æt 36, married, with healthy children and good family history Never had syphilis Present trouble began a year ago Changes in weather produced pains in the parts which have since become affected To relieve these firm pressure was made with the hand Between the paroxysms pain was not produced by pressure Later the lesions presented themselves

Present Condition —A strong, hearty man, a peddler by occupation The pains still persist, recurring at intervals of one night to a week Each attack lasts two or three minutes, and does not return the same night The growth is situated on the right side of the back, in the mid dorsal region, and the course of the growths is obliquely outwards There are one or two of the elevations on the left side, three of the growths are as large as peas, others are small The epidermis is not abnormal On passing the hand over these growths there is no hyperæsthesia, but on deep pressure in the neighborhood of the larger masses the patient sinks moaning to the floor One of the larger growths was removed, and microscopical examination showed it to be composed of smooth muscular fibre

From a clinical standpoint, the case bears a close relation to the cases of neuroma which have been reported The speaker concluded that certain new growths in the skin, accompanied with severe pain, may be widely different histological structures We are not justified in assuming that a painful tumor of the skin is a neuroma or fibro-neuroma simply from its clinical history, without a microscopical examination

Dr Duhring said it would be difficult to differentiate, from the local appearances, the case described by Dr Hardaway, and that which he reported some years ago It is not possible from a clinical standpoint, as has been said, to differentiate these growths, and it was necessary to rely on the microscope There is one point, and that is in the case just described, no pain was produced by superficial manipulation, while in his case the pain was intense on the slightest touch, while firm pressure decreased the pain

Dr R B Morrison, of Baltimore, reported

AN UNUSUAL CASE OF TYLOSIS OF THE HANDS

The patient was a negro, aged 32, muscular, well developed, and apparently healthy By occupation he was a fireman of a steamer, and had occupied this position for ten years, shoveling coal with the right hand grasping the upper portion of the shovel, and the left hand sliding up and down the handle Two fingers of the left hand are worn off to the second joint, while the other two are going in the same way, the nails having nearly disappeared On several occasions he has drawn pieces of bone from the fingers There has been no pain at all connected with the affection On this hand there are some large blisters, underneath which there are red granulating surfaces, which are painless There is no history nor evidence of syphilis Specific treatment has been used without effect The man obstinately refuses to give up his work, so that little could be done in the way of treatment

Dr. Tilden thought there was a good deal of resemblance between this case and the cases of perforating ulcer of the foot, and this would lead to suspect a nervous element,

Dr Morrison had been led to consider it a strictly local affection, from the fact that the hand which was most exposed to rubbing and to the heat of the furnace, was the one most affected

Dr Duhring would be inclined to consider the callosities a secondary condition The occupation probably had something to do with the aggravation of the disease, but if the occupation had been different there would probably have been a similar change He would regard it as dependent on some deep change in connection with the nerves similar to that which occurs in perforating ulcer of the foot

Dr Morrison thought that as an affection of the nerve in the first place, he could hardly admit It may be that the continued congestion of the skin, dependent on his occupation, produced changes in the nerves or other part, which culminated in this affection In referring to the literature of the subject, he had found similar cases attributed to mechanical irritation

EVENING SESSION

Dr L A Duhring read a paper on

THE RELATION OF HERPES GESTATIONIS AND CERTAIN OTHER FORMS OF DISEASE TO DERMATITIS HERPETIFORMIS

Attention was briefly directed to the previous articles of the reader on dermatitis herpetiformis, and to a paper showing its identity with the impetigo herpetiformis of Hebra, also to a preliminary note on the relation of this disease to herpes gestationis and other similar forms of cutaneous disease, read before the Association at the last meeting

The object of the present communication was to prove the identity of so-called herpes gestationis with the vesicular variety of dermatitis herpetiformis, and to show that the term herpes gestationis was a misnomer, the affection being found in men as well as in women Secondly, that certain other so called forms of herpes, such as "herpes pemphigoide," "herpes vegetans," "herpes pyæmicus," etc, as well as certain cases regarded by the reporters as "peculiar forms of pemphigus," must be viewed as examples of this disease, and finally, that instances of the same affection were also met with in literature under the title of hydroa and under divers other captions Numerous cases from English, French and German literature were cited The paper of Dr Duhring was stated to be looked upon as supplementary to the preliminary note referred to, and embodied the results of considerable research into literature If the views put forth proved to be correct, a great deal had been gained for dermatology in bringing these peculiar forms of disease together

Dr J C White considered the term dermatitis herpetiformis a misnomer The disease should be called dermatitis multiformis The herpetic element is often wanting

Dr A R Robinson agreed with Dr White that the term dermatitis herpetiformis is too restricted, but he would prefer some term which does not indicate the pathology, until the disease is better understood

Dr J Nevins Hyde thought the term dermatitis herpetiformis is preferable, if for no other reason, because it is suggestive

Dr G H Fox showed here a photograph of a case of erythema multiformis, which might be mistaken for dermatitis herpetiformis This disease shoule be placed in strong contrast with dermatitis herpetiformis

Dr Duhring said the name dermatitis herpetiformis was adopted because it seemed the least objectionable The herpetiform character of the disease was characteristic The term dermatitis multiformis is already employed to designate a form of skin trouble

Dr G H Tilden, of Boston, read a paper on

MYCOSIS FONGOIDE

He described the case of a man, aged 28 years when he came under observation Three years before, several red, desquamating spots had been observed on the elbows Several months later, erythematous spots accompanied with pruritus were noted These lesions retained a dry, scaly character There were no vesicles or pustules At the end of a year, several red nodules appeared on the face and throat These, however, disappeared Later, a small papule appeared on the right thigh and increased in size From this there exuded a thin fluid This was followed by the development in many parts of the body, particularly the axillæ, groins and neck, of similar lesions, in some cases reaching the size of a hen's egg After a time there was superficial erosion of some of the tumors, but these excoriated tumors remained firm in consistence But some of the masses which were covered with epidermis were soft, but there was no evidence of the formation of pus There was also indolent enlargement of the lymphatic glands The general health continued good The patient passed from observation and died at the end of three years and a half

The report of the microscopist who examined the tumors was read His opinion was that the growths consisted of the formation of lymph tissue in corium

Reference was then made to the literature of the subject and the various cases, some 30 in number, which had been reported, were given, and the symptoms and course of the disease described Sections of the growth were also presented for examination

Dr White said that this patient was under his care during the last stages of the disease, and he presented the changes which had been described Some of the larger growths disappeared During the last months of his life the man was taking arsenic Death resulted from the occurrence of diarrhœa

Dr G H Rohe had seen a case four years ago of what he thought was the same affection The man, 62 years of age, had a multitude of these tumors Several had been extirpated before he came under observation, but there was recurrence with this fungoid appearance The man was given arsenic, but he died from exhaustion No autopsy could be obtained As far as could be detected, there was no affection of the liver or spleen

DR MORRISON had seen a similar case which was diagnosed multiple sarcoma of the skin It takes the microscope to settle the question in these cases

DR FOX had seen one or two similar cases in New York He suggested the use of calamooga oil Judging from its effects in other cases, it should be useful

DR HARDAWAY said that in a case of alveolar sarcoma, which he had reported, the disease had existed fifteen years, but the clinical features were about the same as they were years ago There is marked enlargement of the lymphatic glands The general condition is good

DR HEITZMAN, said that the description of the microscopic appearance is that of a lympho sarcoma, and the examination of the specimen confirmed him in the view that this was a case of lympho sarcoma

DR S SHERWELL, to show the amount of involution that may take place, referred to a case of melano-sarcoma under his care The man was treated with arsenic, mercurials, etc After six months treatment, the tumors almost disappeared There was not the slightest evidence of syphilis

DR FOX said in regard to the use of calamooga oil, that he had seen it used in a case of leprosy, and there was now not a trace of leprosy, except the contraction of the fingers which is, however, a secondary condition It has failed in many cases, but there is sufficient to justify a trial of it in the chronic inflammatory affections referred to

DR L N DENSLOW, of St Paul, read a paper on

URETHRAL IRRITATION IN THE MALE AS A CAUSE OF CERTAIN NEUROSES AND OF ACNE

He prefaced his remarks by a brief review of the cases of contracted meatus reported by Dr Otis He than gave an account of a number of cases coming under his observation, in which there were reflex conditions associated with conditions of the uretha, such as contracted meatus, stricture and excessive sensitiveness of the prostatic urethra In these cases removal of the urethral trouble produced an alleviation or cure of the affection to which attention had been directed He also reported four cases of severe acne in which the same treatment had been followed by marked improvement or cure of the skin disease In some of the cases ergotine was also employed The speaker said that he simply reported the cases as so many observed facts, and did not express any theory He would keep the cases under observation and at a subsequent meeting give a further report

DR WHITE had employed ergot in obstinate cases, without seeing the least benefit from its use

DR TAYLOR objected to this promiscuous cutting of urethras which is so common at present

DR SHERWELL believed that acne is largely a reflex disorder, but he was not in the habit of introducing a sound in every case of acne It is valuable in severe cases He believed in the action of ergot in connection with local applications, especially in females

DR HYDE said, that many of these cases with urethral trouble associated with acne, are patients who probably have been taking for some time, balsamic preparations, and as a result they have the development of acne

DR DENSLOW said, that in all the cases reported, the acne had existed since puberty The patients were not hypochondriacs, and they were not masturbators He was satisfied that no drugs had been used in any of them

(*To be concluded*)

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Cancer Hospital—The Skin and Cancer Hospital—Deaths from Cancer in the past Decade—A Case of Yellow Fever—Death of Mr David Colden Murray

The first annual report of the New York Cancer Hospital, which has recently been published, contains a beautiful representation of its very handsome and commodious buildings, now in course of erection on Eighth Avenue, opposite Central Park between 105th and 106th Sts It was from discussions in the Woman's Hospital in this city that the scheme for the new institution originated The result of these discussions was an offer from Mr John Jacob Astor (his name not being mentioned) of a fund for the erection of a pavilion on the grounds of the Woman's Hospital for the treatment of cancer patients The acceptance of that offer was under consideration by the Woman's Hospital for nearly a year, when it was deemed unwise to carry out the project In the meantime, the late Mrs General Cullum, a lady of large means, with some others cooperating with her, in ignorance that it was Mr Astor who had made the offer to the Woman's Hospital, had been considering the independent organization of a cancer hospital The outcome of the matter was a conference between Mrs Cullum, on behalf of herself and those who were acting with her, and the friends of Mr Astor whom he had asked to cooperate with him, and eventually the transfer by Mr Astor of his offer to a separate hospital, to be organized for the exclusive treatment of cancer Up to the present time, the report states, the new hospital has received in money in all $308,572, a part of which is appropriated as a free-bed fund In addition to this, by the will of Mrs Cullum there are devised to the hospital lots belonging to her of the assumed value of $35,000, and a valuable property in San Francisco which is not immediately available

This is certainly an excellent showing for so youthful an institution, but at the same time it is greatly to be regretted that its founders and managers should have directed all their energy towards the organization of an independent cancer hospital, when there had already been in successful operation in the city for three or four years an institution devoted to exactly the same ends This was the New York Skin and Cancer Hospital, towards the support of which the great annual "Kirmess" at the Metropolitan Opera House always brings in such a handsome sum It is true that at this hospital diseases of the skin, as well as cancer, are treated, but it must not be forgotten that at such an institution the vast mass of those suffering from skin affections are out-patients Very few of these ever become in-patients, so that the wards are devoted almost exclusively to those affected with cancer Practically, therefore, all the advantages claimed for the newer institution in affording the best facilities for the most approved methods of treatment of cancer cases are to be met with at the older one already in active operation

For some years the New York Skin and Cancer Hospital has had a building on 34th St with a limited number of beds for in patients, and during the past eighteen months the institution has purchased quite a large and very desirable tract of land a short distance out of town, on which it is proposed to erect buildings which will offer ample accommodations for all suitable cases which may apply for admission The only thing which prevents the immediate carrying out of the plans of its managers is the lack of the necessary funds, and it is melancholy to reflect that if the friends of the New York Cancer Hospital, instead of attempting to found a second institution of the same character, had given their generous donations to the one already organized, we should have had by the present time or in the immediate future, a cancer hospital of which New York might well have been proud, and which would at once have been of more practical benefit to the community than will probably be possible in the case of either of these institutions for many years to come Instead of this, both of them are much crippled for want of means The older organization has not yet accumulated a sufficient fund to build, and the newer one, while it has one admirable building nearly completed, is as yet without the means necessary to open it successfully From the report referred to we learn that preparatory to opening there must be an engine house with its equipment and accessories, furniture must be provided and the grounds must be put in order, while the money to do this is still lacking Furthermore, as the building now in process of erection is exclusively for females, there must be another for males, and a chapel building is also contemplated It is said that when the authorities of the New York Skin and Cancer Hospital first learned of the plan to start another cancer hospital, they did all in their power to induce the founders of the latter to join forces with them, offering them a liberal share in the management, etc , but their proposition was rejected, and consequently we see the present unfortunate waste of energies resulting

While on the subject of cancer hospitals, it may be of interest to know that Dr John T Nagle, of the Bureau of Vital Statistics, has lately prepared from the records at the Health Department a table of the deaths from cancer during the past ten years From this it appears that in 1874 there were 416 deaths from this cause, of which 3 were from cancer of the throat, 4 from cancer of the tongue, and 7 from cancer of the mouth, while in 1884 there were 725 deaths from cancer, of which 9 were from cancer of the throat, 1 from cancer of the tongue, and 9 from cancer of the mouth The total number of deaths from cancer in the last ten years was 6,012, of which 47 were from cancer of the throat, 17 from cancer of the tongue, and 82 from cancer of the mouth

A fatal case of yellow fever has recently occurred in this city, the patient being a stowaway who arrived on a vessel from Cuba The bark John Gibson, on which he came, was passed through quarantine several days before he was attacked with the disease, on the strength of a bill of health given by the surgeon in charge at the Delaware Breakwater The Gibson left Cienfuegos, Cuba, with all well on board, but when she had been some days at sea yellow fever broke out among the crew The master died, and was buried at sea, and the first mate, the cook and two sailors also had it, but all recovered During the prevalence of the sickness two stow-aways were discovered, one of whom was attacked some days after landing at New York, as mentioned above At the Delaware Breakwater the vessel was cleansed amd fumigated, and the cook was retained in hospital

New York has lost one of her most estimable citizens by the death of Mr David Colden Murray, which occurred at the New York Hospital last week from tumor of the bladder Mr Murray was formerly a well known shipping merchant, and the old Murray line of steamships running between this port and Savannah was named after him He was a descendant of the distinguished medical Lieutenant-Governor of colonial times Cadwalader Colden, and a son of the late Robert I Murray, who was Secretary of the New York Hospital Association from 1824 up to the time of his death in 1858 Mr Murray succeeded his father in this position, which he retained up to his own death, so that the secretaryship was held continuously by father and son for sixty one years He was made one of the Governors of the hospital in 1853, and became Treasurer of the New York Dispensary in 1856, continuing this duty until one year ago Mr Murray was devoted to the interests of these institutions, and was greatly beloved and respected in the community P B P

NECROLOGY

GEORGE B FUNDENBERG, M D

Dr George B Fundenberg, of Pittsburgh, Pa , died at Somerset, Pa , on August 15, after a protracted and painful illness

Dr Fundenberg was born in Lewistown, Frederick county, Md , November 17, 1815 He was the second son of Daniel Fundenberg and Rebecca Fahnstock His grandfather was a physician, as well as his only two brothers, the one being a well known dentist of Pittsburg

Dr Fundenberg's mother, in 1830, after the death of her husband, moved to Pittsburgh, where her son entered upon the study of medicine in the office of Dr Jos Gazzam Subsequently he graduated at the "Pennsylvania Medical College," and began the practice of medicine with his brother-in-law, Dr S P Hullihen, at Wheeling, W Va , a few years later he returned to Pittsburgh and soon afterwards located in Ligonier Valley, Westmoreland county In 1849 he again returned to Wheeling, where he practiced his profession two years In 1851 he located in Somerset, Somerset county, Pa , where he practiced for nearly ten years In the fall of 1860 he moved to Cumberland, Md Here he resided for twenty years, and, as in all his former years, proved himself proficient and eminently successful as a medical man During his residence at Cumberland the Civil war broke out, and he received an appointment from Governor Curtin, of Pennsylvania, as surgeon of the One Hundred and First Pennsylvania Regiment Subsequently he was transferred to the Twenty-Third Regiment Soon afterwards was made Brigade Surgeon, but on account of ill health was compelled to decline all active duty, and was placed in charge of the large Military Hospital in Cumberland, Md For some years was president of the Alleghany County (Maryland) Medical Society He was twice chosen President of the Board of County School Commissioners of the same county

In April, 1881, Dr Fundenberg moved to Pittsburgh, where he continued to practice his profession until his death He leaves a widow and eight children, five daughters and three sons, all of the sons having chosen their father's profession The universal testimony of all who knew him was that he was a man of eminent worth He was a man of recognized ability in his profession, being for a score of years a frequent contributor to the medical journals of the country His last contribution to the literature of his profession was an article on "The Treatment of Uterine Flexures by the Intra Uterine Stem," which was read before the American Medical Association at its late annual meeting, and published in the Journal of September 5

MISCELLANEOUS

Disinfection of Canadian Mails —The Post-office Department at Washington, in view of the prevalence of small-pox in Canada, has requested the Secretary of the Treasury to have all mails from Canada to the United States thoroughly disinfected

The Society of Hygiene, of Paris, has awarded honorary diplomas to Drs H P Walcott Charles Folsom, and S W Abbott, of Massachusetts, for their labors in promoting public health

Dr B R H Auger, the well-known surgeon of the Larboisière Hospital in Paris, has been visiting in New York, and has been the recipient of considerable attention here He arrived on the *Amerique*, and will visit Japan, China, and the East Indies before returning to France

Dr P O Hooper, of Arkansas, President of the Board of Trustees of the State Lunatic Asylum, has been elected Superintendent of that institution, *vice* Dr C C Forbes, who has resigned on account of ill health The appointment is a most excellent one

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM AUGUST 20 1885 TO SEPTEMBER 4 1885

Magruder, D L , Lieutenant Colonel and Surgeon, granted leave of absence for fifteen days (S O 201, A G O , Sept 3 1885)

Middleton, Passmore, Major and Surgeon, assigned to duty as attending surgeon at these headquarters, vice Major J V D Middleton, Surgeon, hereby relieved (S O 131, Dept of the Missouri, Aug 28, 1885)

Cronkhite, H M , Capt and Assistant Surgeon, relieved from duty at Ft Reno Ind Ter , and assigned to duty as post surgeon, Ft Hays, Kansas (S O 129, Dept of the Missouri, Aug 26, 1885)

Girard, Alfred C , Capt and Assistant Surgeon, assigned to duty as post surgeon at Boise Barracks, Idaho Ter (S O 142, Dept of the Columbia, Aug 22, 1885)

Davis, Wm B , Capt and Asst Surgeon, having reported for orders from leave of absence, assigned to duty at Fort Porter, N Y , as post surgeon (S O 183, Dept of the East, Aug 28, 1885)

Powell, J S , Captain and Asst Surgeon, relieved from temporary duty at Ft Leavenworth, Kan , and assigned to duty as post surgeon at Ft Lyon, Colo (S O 128, Dept of the Missouri, Aug 25, 1885)

Banister, Jno M , Capt and Asst Surgeon, assigned to temporary duty at Camp of Competitors at Creedmoor, N Y , arriving not later than Sept 4 1885 (S O 58, Div of the Atlantic, Aug 31, 1885)

McCaw, W D First Lieutenant and Asst Surgeon, assigned to temporary duty at the Camp of the Troops near Kiowa, Kan (S O 128, Dept of the Missouri, Aug 25, 1885)

Kendall, Wm P , First Lieutenant and Asst Surgeon (recently appointed), to report in person to the commanding general Dept of California for assignment to duty (S O 201, A G O , Sept 3, 1885)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING SEPTEMBER 5 1885

Henry Stewart, Surgeon leave of absence extended one year from Oct 15, with permission to remain abroad

John M Steele, P A Surgeon, detached Sept 1 from Constellation, and report for duty at Naval Academy, Annapolis, Md

Geo A Bright, Surgeon, detached Sept 1 from Constellation, and wait orders

S H Dickson, P A Surgeon, ordered to Naval Academy, Annapolis, Md , as relief of P A Surgeon A A Austin

Henry B Fitts, Asst Surgeon, detached from coast survey steamer "Gedney," and wait orders

A A Austin, P A Surgeon, detached from Naval Academy, Annapolis, Md , and ordered to coast survey steamer Gedney to relieve Asst Surgeon H B Fitts

ORIGINAL ARTICLES

STATE MEDICINE[1]

BY FRANK S BILLINGS, M D,
PATHOLOGIST TO THE NEW YORK POLYCLINIC SCHOOL OF MEDICINE

The views expressed in this paper will be found ultra in the extreme, but as I have given over ten years earnest study to the subject of State Medicine, not only in books, but practically in other countries than our own and as they are the result of such study and honest conviction, I trust they will receive the attention which the subject at least deserves
